# Appointments.

*Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to* THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

BARGE, H. F., has been appointed Dental House Surgeon to Guy's Hospital.

BREWIS, R. ADAMS, M.D. Edin., has been appointed Medical Officer of Health for the Dursley Rural District Council.

DIGHTON, CHARLES ADAIR, M.B., F.R.C.S. Edin., has been appointed Honorary Assistant Surgeon to the Eye and Ear Hospital, Myrtle-street, Liverpool.

FINCH, G., M.R.C.S., D.P.H., has been appointed Assistant School Medical Officer to the East Sussex County Council.

GLOVER, F. S., has been appointed Dental House Surgeon to Guy's Hospital.

HAILES, CLEMENTS, M.D., F.R.C.S. Edin., has been appointed Consulting Surgeon to the Bristol Eye Hospital.

MCGRATH, MATHEW J., M.B., B.Ch., B.A.O. R.U.I., has been appointed Assistant Medical Officer at Brislington House Private Asylum, near Bristol.

MOISER, LIONEL HENRY, M.B. Lond., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer of Health by the Crediton (Devon) Urban District Council.

OGILVY, ALEXANDER, M.D. Dub., F.R.C.S. Irel., has been appointed Surgeon to the Bristol Eye Hospital.

STOCK, WILLIAM S. V., M.B., B.S. Lond., F.R.C.S. Eng., has been appointed Anæsthetist to the Bristol Eye Hospital.

WOTTON, W. H., has been appointed Dental House Surgeon to Guy's Hospital.

WRIGHT, ANDREW J. M., M.B., B.S. Lond., F.R.C.S. Eng., has been appointed Rhinologist to the Bristol Eye Hospital.

# Vacancies.

*For further information regarding each vacancy reference should be made to the advertisement (see Index).*

BIRMINGHAM CORPORATION CITY HOSPITAL, Lodge-road.—Assistant Resident Medical Officer. Salary £120 per annum, with board, residence, &c.

BOLTON INFIRMARY AND DISPENSARY.—Third House Surgeon. Salary £90 per annum, with apartments, board, and attendance.

BURSLEM, HAYWOOD HOSPITAL.—Resident Medical Officer (female). Salary £100 per annum, with board, residence, and laundry.

CHELTENHAM EYE, EAR, AND THROAT FREE HOSPITAL.—House Surgeon. Salary £200 per annum.

CROYDON, COUNTY BOROUGH OF.—Assistant Medical Officer. Salary £250 per annum.

DARTFORD UNION WORKHOUSE AND CHILDREN'S HOME. — Medical Officer. Salary £150 per annum.

DISTRICTS OF NESTING AND LUNNASTING, PARISH OF NESTING, &C.—Medical Officer. Salary £50 per annum.

EDINBURGH ROYAL INFIRMARY.—Superintendent. Salary £600 per annum, with house, coal, and light.

GREAT YARMOUTH HOSPITAL.—House Surgeon, unmarried. Salary £100 per annum, with board, lodging, and washing.

HALIFAX UNION POOR-LAW HOSPITAL.—Resident Medical Officer. Salary £110 per annum, with apartments, rations, and washing.

HAMPSTEAD GENERAL AND NORTH-WEST LONDON HOSPITALS.—Surgeon to Out-patients.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.—Resident Medical Superintendent. Salary 100 guineas per annum, with board and residence. Also Anæsthetist. Salary £15 15s. per annum.

HOSPITAL FOR WOMEN, Soho-square, W.—Resident Medical Officer for six months. Salary at rate of £60 per annum.

HOSPITAL OF ST. JOHN AND ST. ELIZABETH, 40, Grove End-road, London, N.W.—Resident Medical Officer for six months. Salary at rate of £80 per annum, with board, residence, and washing.

LEAMINGTON, WARNEFORD, LEAMINGTON, AND SOUTH WARWICKSHIRE GENERAL HOSPITAL.—Junior Resident Medical Officer. Salary £65 per annum, with board, washing, and apartments. Also Honorary Physician.

LEEDS PUBLIC DISPENSARY.—Junior Resident Medical Officer. Salary £100 per annum, with board and lodging.

LEEDS UNION, Beckett-street.—Assistant Medical Officer (female), unmarried. Salary £100 per annum, with board, washing, apartments, and attendance.

LIVERPOOL, DAVID LEWIS NORTHERN HOSPITAL.—Three House Surgeons for six months. Salaries at rate of £60 per annum, with residence and maintenance.

LLANYBYTHER, CARMARTHENSHIRE, WEST WALES SANATORIUM.—Medical Superintendent. Salary £250 per annum, with board and residence.

MAIDSTONE, WEST KENT GENERAL HOSPITAL.—Assistant House Surgeon, unmarried. Salary £80, with board and residence.

MANCHESTER, ST. MARY'S HOSPITALS FOR WOMEN AND CHILDREN.—House Surgeon. Salary at rate of £50 per annum, with board and residence.

NEWCASTLE-UPON-TYNE DISPENSARY.—Visiting Medical Assistant. Salary £160 per annum.

NEWCASTLE-UPON-TYNE, ROYAL VICTORIA INFIRMARY AND THE UNIVERSITY OF DURHAM COLLEGE OF MEDICINE.—Assistant to Professor of Pathology. Salary £150 per annum.

NEWCASTLE-UPON-TYNE UNION WORKHOUSE. — Assistant Resident Medical Officer, unmarried. Salary at rate of £150 per annum, with apartments, rations, and washing.

NEWCASTLE-UPON-TYNE, UNIVERSITY OF DURHAM COLLEGE OF MEDICINE.—Lecturer on Physiology. Salary £200 per annum.

NEWPORT AND MONMOUTHSHIRE HOSPITAL.—House Surgeon. Salary £60 per annum, with board, residence, and laundry.

NOTTINGHAM WORKHOUSE INFIRMARY. — Assistant Resident Medical Officer, unmarried. Salary £130 per annum, with apartments, board, washing, and attendance.

QUEEN'S HOSPITAL FOR CHILDREN, Hackney-road, Bethnal Green, E.—House Surgeon for six months. Salary at rate of £80 per annum, with board, residence, and washing.

RANSOM SANATORIUM FOR CONSUMPTIVES, Sherwood Forest, near Mansfield, Notts.—Resident Medical Officer (female). Salary £100 per annum, with board, residence, and washing.

ROYAL NAVAL MEDICAL SERVICE.—Twelve Commissions.

ST. PAUL'S HOSPITAL FOR SKIN AND URINARY DISEASES, Red Lion-square, W.C.—Three Clinical Assistants.

ST. PETER'S HOSPITAL FOR STONE, &C., Henrietta-street, Covent Garden, W.C.—Junior House Surgeon for six months. Salary at rate of £50 per annum.

SHREWSBURY, SALOP INFIRMARY.—House Physician. Salary at rate of £70 per annum, with board and apartments.

STOCKPORT INFIRMARY.—Junior House Surgeon. Salary £80 per annum, with board, washing, and residence.

TRURO, ROYAL CORNWALL INFIRMARY.—House Surgeon, unmarried. Salary £100 per annum, with rooms, board, and washing.

WEST BROMWICH DISTRICT HOSPITAL.—Assistant Resident House Surgeon, unmarried. Salary £75 per annum, with board, residence, and washing.

WEST-END HOSPITAL FOR NERVOUS DISEASES, 73, Welbeck-street, W.—Clinical Assistants. Also Clinical Pathologist for six months. Salary at rate of £50 per annum.

WEST LONDON HOSPITAL, Hammersmith-road, W.—Honorary Medical Registrar. Also Two House Physicians and Three House Surgeons for six months. Board, lodging, and laundry allowance provided.

WINCHESTER, ROYAL HAMPSHIRE COUNTY HOSPITAL. — House Physician.

THE Secretary of State for the Home Department, Whitehall, S.W., gives notice of a vacancy for a Medical Referee under the Workmen's Compensation Act, 1906, for the County Courts of Croydon and Epsom.

# Births, Marriages, and Deaths.

## BIRTHS.

ARKLE.—On Dec. 21st, 1910, at Dugan-street, Kalgoorlie, Western Australia, the wife of J. Vere Arkle, F.R.C.S. Eng., of a son.

DINGLE.—On Feb. 4th, at Tyn-y-coed, Barmouth, N. Wales, the wife of Harry Dingle, M.R.C.S. Eng., L.R.C.P. Lond., of a son.

LOW.—On Friday, Feb. 3rd, at 146, Harley-street, W., the wife of V. Warren Low, M.D., F.R.C.S., of a daughter.

STEDMAN.—On Jan. 26th, at Southwold-road, Upper Clapton, N.E., the wife of Savignac Bell Stedman, M.R.C.S., L.R.C.P., of Norwood, Ceylon, of a daughter.

## DEATHS.

HODGSON.—On Feb. 3rd, suddenly, Gerald George Hodgson, M.R.C.S. Eng., L.S.A., aged 50 years.

SILVER.—On Jan. 26th, at the Old Rectory, Sutton-at-Hone, Kent, Ebenezer David Silver, M.D. Aberd., I.M.S., aged 91 years.

***N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.***

# Notes, Short Comments, and Answers to Correspondents.

## AMERICAN FOOTBALL.

*To the Editor of* THE LANCET.

SIR,—The late visit of the United States battle fleet was probably the first occasion on which American football has been played by American teams in England. The verdict of the spectators was unhesitating. Even as a spectacle, once the novelty was gone, the game was vastly inferior to good Rugby Union play, whilst as a contest of skill, and particularly as a contest of true sportsmanship, it compared even worse. It has other and, I think, graver disadvantages. Despite the inauguration of what is known as "new football" in 1905, football continues to claim a great number of victims from amongst the finest athletes of the nation. In 1906 Dr. Coughlin, in the *Medical Record*, N.Y., summarised the football casualty list for the preceding year, and found that at least 26 deaths were directly due to football. Dr. Coughlin's list included the following cases of fatal injuries in 1905:—

| | |
|---|---|
| Abdominal injuries ... ... ... ... ... ... ... | 7 |
| Fracture of skull ... ... ... ... ... ... ... | 5 |
| Concussion of brain ... ... ... ... ... ... ... | 5 |
| Fracture of spine ... ... ... ... ... ... ... | 1 |
| Dislocation of spine with paralysis ... ... ... ... | 3 |
| Cerebral hæmorrhage ... ... ... ... ... ... | 2 |
| Acute peritonitis ... ... ... ... ... ... ... | 1 |
| Fracture of rib, broken end being driven into the heart ... | 2 |

In 1906 the *Chicago Tribune* found that football had caused 11 deaths and 103 cases of serious injury. In 1907 there were also 11 deaths and 97 cases of serious injury. The *New York American* has summarised the next three seasons, and the figures as quoted by Dr. Clurman in the *Medical Record* are as follows: in 1908 there were 13 deaths and 84 serious non-fatal injuries; in 1909 33 deaths and 216 injuries, 73 of which were classified as serious; in 1910 there were 19 deaths and 400 injuries not classified.

In addition, Professor James of Illinois has stated that "nearly all football players have weak hearts and are more liable to diseases of other forms than men who exercise moderately." English Rugby has the great disadvantage of leaving many of its devotees with weakened knees and shoulders, a serious fault scarcely sufficiently appreciated, but compared with these American records its history is as the white flower of a blameless life. The Minotaur of Knossos achieved his unenviable reputation by devouring each year seven Athenian youths and maids, but this demoralising and brutal game far exceeds him in its yearly sacrifice of life and health in America of the present day.

The spirit of commercialism threatens English Rugby, and English football is not free to-day from other blemishes. There is too much of the spirit which causes 30,000 spectators to watch paid and professional players do battle for their respective limited liability companies. Football tends to degenerate, even here, from a game into a gladiatorial spectacle. Rough play and semi-intentional fouls are far too common.

Let us read aright the lessons of these American figures and set our own house in order, although it may seem somewhat cleaner than our neighbour's.

I am, Sir, yours faithfully,

Feb. 4th, 1911. SPORTSMAN.

## BOY SCOUTS AND THE PREVENTION OF TUBERCULOSIS.

WE have before had occasion to notice *The Boy Scouts (Baden Powell's) Head Quarters Gazette*, the magazine of an organisation that is undoubtedly doing much to implant in the youth of the coming generation the spirit of discipline, of self-help, of loyalty, the love of nature, and the love of country—qualities that in the past made England great, and must be reanimated if England is to remain so. The December issue shows also that from a purely sociological point of view the organisation can be used to further many desirable movements, about the expediency of which there can be no division of opinion. It contains an article entitled "A Great National Work for Scoutmasters," which lays down some sensible lines on which the Scout movement can become active for good in the fight against consumption by spreading the knowledge of the germ doctrine, of nose breathing, ventilation, cleanliness, sterilisation, the avoidance of spitting, and of the practice of forethought by insurance at a low premium. Consideration for others is impressed by instructions to stop the bands on such occasions as the following: when passing hospitals or churches during service, in streets after dark when children are in bed, or in which there is illness, and on meeting nervous horses.

## DR. GRENFELL'S WORK IN LABRADOR.

THE unostentatious but valuable services of Dr. Wilfred T. Grenfell to civilisation in Labrador have several times received mention in these columns, but his presence in England on a brief but well-earned vacation again calls attention to his work. Since 1893, when Dr. Grenfell began his medical missionary work with a 90-ton sailing vessel in Labrador, with all the attendant difficulties of an enormous coast-line poorly charted, inclement weather, and a widely scattered population, great progress has been made. The severities of isolation have been mitigated by the establishment of a chain of centres, with four hospitals, five resident medical officers, and a staff of lady nurses; while poverty has been ameliorated by the introduction of coöperative stores and the replacement of barter by a cash system, and by the introduction of lumbering, weaving, clay-moulding, peat-cutting, and farming, as useful and remunerative occupations during what used formerly to be periods of enforced idleness. An effort is being made to replace the enormous number of dogs, which have hitherto been necessary for winter driving, by reindeer. This will render more practicable the introduction of cattle. On the whole, Labrador is healthy, much like Norway, but the insanitary habits of the people in their dwellings afford conditions suitable for the spread of tuberculosis, which is rife among the people, notwithstanding their outdoor life. A large institute is now being erected as a correcting influence to the saloons. Dr. Grenfell's work is of the eminently practical kind, and the medical profession has reason to congratulate itself that so much good administrative work is being done by one of its members.

## ENCEINTE.

*To the Editor of* THE LANCET.

SIR,—All the French etymologists I have read (Littré, Brachet, Scheler, Pourret, Landais, Laveaux, Gattel) say *incincta*, or *non cincta*. Scheler, however, discusses that origin and refers to the Spanish: *estar en cinta*, to be double; and to the Italian: *incignere*, *encenher*, to make big. French has *grosse*, *engrosser*, *enceinturer*, to make pregnant. But against "Blancus's" opinion for *cloister* we must note that *in*, in Latin, if it means without, means also inside, wherefrom comes the *substantive enceinte*, that which encloses (*enceinte* applied to a woman is an *adjective*). Ménage, in his "Dictionnaire Etymologique," derives the word from *inciens*.

Besides, I would remark that the child, not the woman, is "*cloistered*." Moreover, the old engravings, for instance, the engraving to be found in "Hebammen Buch" of J. Rueff, Frankfort, 1583, called "La Visite à la Sage-femme," represents the woman without a girdle.

I am, Sir, yours faithfully,

Geneva, Jan. 19th, 1911. A. CORDES.

## HEALTH MATTERS IN JAMAICA.

A REPORT by the Governor, Sir Sydney Olivier, K.C.M.G., on the Blue-book of the colony for the year ended March 31st, 1910, has been received at the Colonial Office and ordered to be presented to Parliament. In the section devoted to vital statistics the estimated population is set down at 862,422—421,056 males and 441,366 females. The number of marriages during the year was 3543, the rate (4·1) per 1000 of population the same as in the previous year, and corresponding with the average prevailing during the five years preceding the earthquake of Jan. 14th, 1907. The abnormal rates of 1907-08 (7·4) and 1906-07 (6·6) were due to the emotional effects of that calamity. The effect of the same incident on the proportion of illegitimate to legitimate births would appear to be also waning, as the percentage of illegitimate births amounts this year to 62·00, against 60·59 in 1908-09, and is approaching the average rate of 63·5 which has prevailed during the past ten years. The total births registered numbered 32,402, against 31,785 in the previous year, the rate per 1000 of estimated population being 37·8, against 37·6.

The number of deaths registered was 18,636, being 21·7 per 1000 of the estimated population, the lowest death-rate since 1902-03, when it was 19·8. In 1908-09 the rate was 22·4 and the average of the past ten years has been 23·3. There were 5657 deaths of children under one year of age. In 12,600 out of the 18,636 deaths registered the causes of death are stated, whilst 6036, or about 32·4 per cent., are returned as due to ill-defined or not specified causes. Thus in only about two out of three cases is any definite account received of the cause of death. There were medical certificates in 4134 cases, and coroners' certificates in 219; total 4353 out of 18,636, a little over 23·3 per cent. of the whole. In other cases the cause of death is stated on the authority of the registrar after such inquiries as he has thought it necessary to make. Whilst, however, more than three out of four cases of the deaths recorded are not medically certified, it is not necessary to infer that so large a proportion of these died without medical attendance. In a great number of cases a medical man is called in once or oftener during the illness, but is not applied to for a certificate of the cause of death.

The highest number of deaths attributed to any one specified cause is 1715, returned under "Convulsions," presumably almost entirely deaths of infants. The list is headed by "Fever, *undistinguished*," 3201 cases, which may be taken as meaning for the most part malaria. From malarial fever so defined only 536 deaths were reported, and of these 113 are attributed to Kingston, where returns are made with much greater accuracy than is to be found in those for other parishes. The manifest excess of this proportion confirms the view that a great many of the deaths from "undefined fever" reported elsewhere were probably cases of malarial fever. It may safely be assumed that the average of deaths from this cause was as high in the

island generally as in Kingston, which has less than one-fifteenth of the whole population. At this rate the deaths from malarial fever in the rest of the island might be estimated at 1700, or for the whole of the island, including Kingston, not less than 1800.

The next most important group is that of 1232 deaths from phthisis, of which 153 cases are returned from Kingston—a very high proportion—indicating the occupation of close and insanitary dwellings in the city.

Enteric fever is credited with 244 deaths throughout the island, of which 88 are recorded in Kingston. There can be no question that this fever is prevalent in Kingston in a higher proportion than in almost any other part of the Island, and that this is due, not to any defect of the water-supply, but to the transmission of infection by flies and possibly, to a certain extent, by milk. In addition to the returns of enteric fever, 10 deaths are reported from epidemic diarrhœa and 661 from choleraic diarrhœa and 159 from dysentery. It may be suspected that the distinction between many of these cases and those formally returned as enteric fever was not very reliable, so far as the country returns are concerned. 184 deaths (88 in Kingston) are reported as due to enteritis and to gastro-enteritis, not epidemic. Deaths from pneumonia are reported as 177, from bronchitis 110, and from Bright's disease 243. The other predominant causes of death are venereal disease 152, parasitism 134 (probably very much understated, as parasitic infection and anæmia are frequently associated with deaths reported as fever), chronic rheumatism 139, and asthma 119.

The disease known as "vomiting sickness," which breaks out in certain districts in the cold months of the year, continues to be a subject of regrettable perplexity to the medical profession. 620 deaths are attributed to what the superintending medical officer calls "the combination of diseases known popularly as vomiting sickness," and he expresses the opinion that many of these cases may be, indeed undoubtedly are, due to ackee poisoning, cassava poisoning, worms, meningitis, bronchitis, gastritis, and other more familiar diseases, but there is little doubt that, beyond these, there remains an unexplained residue which needs investigation.

The reports of the district medical officers vary in fulness, and are not all compiled from the same point of view, but the extent to which particular diseases are mentioned there may be taken as a pretty fair indication of their prevalence and of the importance attached to them by the medical officers. Thus 39 reports were received, in 32 of which reference is made to malarial fever as more or less prevalent, in 14 to yaws, in 13 to enteric fever, in 12 to venereal diseases, and in 10 to vomiting sickness. These diseases (all of which can be prevented or abated by hygienic precautions) may fairly be taken as those which are most troublesome in the community, although there is an immense amount of constitutional derangement owing to indigestion, and a considerable prevalence of phthisis and pneumonia.

## A QUEER SYMPTOM.

*To the Editor of* THE LANCET.

SIR,—With reference to my note in THE LANCET last week (p. 349), I have been giving my patient a course of valerian in the form called bornyval, so far with no benefit. The dose I gave was one "perle" containing 4 minims) three times a day until 25 had been taken; then I increased the amount to four per diem for the next six days. At the end of that time I went back to three daily. My patient has taken 3 × 25 *in toto*, and says I have "completely cured her nervousness." But I have signally failed to "cure" the one thing I hoped to—viz., the hot peppery taste in the mouth.—I am, Sir, yours faithfully,

Jan. 29th, 1911. CAPSICUM.

PS.—Bornyval is stated to be the iso-valerianic acid ester of borneol, preformed as such in the valerian root.

## INQUIRIES FOR HOMES.

As our columns testify, we are constantly receiving inquiries from our readers for homes or institutions to which crippled or mentally defective children or others may be sent. Unless these inquiries state how much per week the parent or guardian can afford to pay, and whether a temporary or permanent home is desired at that rate, very few, if any, useful answers will be received. If it is desired to make the more vague appeal to our readers, correspondents are requested to affix initials and an address to their inquiry. With every wish in the world to be helpful, the task of forwarding the very voluminous correspondence which a vague inquiry may bring to our office is one which we cannot undertake.

## A CONVENIENT EYE DIAGNOSIS CHART.

Mr. Charles A. Adair Dighton, honorary ophthalmic and aural surgeon to the Scarborough Hospital, has sent us a description of an eye diagnosis chart which has been drawn up for him by the Medical Supply Association of Gray's Inn-road, London. It combines the full history of the patient's case on the one side of the sheet, with the fees and treatment on the other, and is made so that it can be easily filed and kept for reference. The advantages of this in consultant work are obvious and the price of the sheets is moderate.

*Ignotus* (M.D.) writes that he will be glad of information as to the chances of employment in Sydney for a capable woman who has received a general and an obstetrical training and who has had large experience of private nursing. The Emigrants' Information Office, 31, Broadway, Westminster, S.W., affords a great deal of this kind of information, but some of our readers may know of a particular opening.

*Individual.*—The circumstances should be brought before the Central Midwives Board, secretary, Mr. G. W. Duncan, at Caxton House, Westminster, London, S.W. If the midwife is on the roll she can be punished by removal; if she has pretended falsely to be on the roll she can be proceeded against legally.

**COMMUNICATIONS not noticed in our present issue will receive attention in our next.**

## A DIARY OF CONGRESSES.

**THE following Congresses, Conferences, and Exhibitions are announced for 1911:—**

**Feb. 20th–25th (Cairo).—Fifth International Congress for the Blind.**
**March 2nd–6th (Berlin).—Thirty-second Balneological Congress.**
**,, 23rd (Paris).—First Congress of French Medical Journalists.**
**,, 28th–April 25th (Tunis).—Exhibition of Hygiene.**
**April 4th–7th (London).—Fourth Annual Nursing and Midwifery Conference and Exhibition.**
**,, 18th–20th (Paris).—Third Congress of Physiotherapy of French-speaking Physicians.**
**,, 18th (Berlin).—Tenth Congress of the German Orthopædic Surgery Society.**
**,, 19th–22nd (Berlin).—German Surgical Congress. (Fortieth Annual Meeting.)**
**,, 19th–22nd (Wiesbaden).—Twenty-eighth German Congress of Internal Medicine.**
**,, 20th–22nd (Groningen).—Thirteenth Nature and Medical Congress.**
**May 30th (The Hague).—International Congress on Opium.**
**May (Washington).—Conference on the Protection of Industrial Property. (Question of False Marking of Goods.)**
**May–October (Dresden).—International Hygiene Exhibition.**
**May–October (London, Crystal Palace).—Festival of Empire Imperial Exhibition. (Profits to King Edward VII. Hospital Fund.)**
**May–October (?) (London, Shepherd's Bush).—Coronation Exhibition.**
**,, (Los Angeles, Cal.).—American Medical Association.**
**June 5th–8th (Kolberg, Prussia).—Fifth International Congress of Thalassotherapy.**
**June and July (Romford).—Town Planning and Modern House and Cottage Exhibition.**
**July (Bergen).—Seventh Norwegian Congress of Internal Medicine.**
**,, (Birmingham).—British Medical Association.**
**July 24th–28th (London).—Second International Congress of Urology.**
**,, 24th–29th (Belfast).—Congress of the Royal Sanitary Institute.**
**August 15th–21st (Dublin).—Royal Institute of Public Health.**
**,, 30th–Sept. 6th (Portsmouth).—British Association.**
**August or September (Berlin).—Third International Laryngo-Rhinological Congress.**
**September (Paris).—First Congress of the International Medical Association for the Prevention of War.**
**,, (Brussels).—Exhibition of Fractures.**
**,, (Turin).—International Congress of Pathology.**
**,, (Genoa).—International Exhibition of Marine Hygiene.**
**September–November (Antwerp).—International Exhibition of Alimentation, Brewing, Wines, and Liqueurs.**
**Sept. 11th–13th (Berlin).—National Congress for the Study and Prevention of Infantile Mortality (*Gouttes de Lait*).**
**,, 11th–16th (The Hague).—Thirteenth International Congress on Alcoholism.**
**,, 18th–23rd (Sydney).—Australasian Medical Congress.**
**,, 18th–24th (Turin).—Fourth National Congress of Hygiene.**
**,, 24th–30th (Rome).—International Congress on Tuberculosis.**
**,, 25th–29th (Rome) Seventh International Congress of Dermatology and Syphilology.**
**October (Cologne).—International Congress of Criminal Anthropology.**
**Oct. 1st–4th (Liége).—Second Congress of Alimentation.**
**Dec. 4th–9th (Havana, Cuba).—American Public Health Association.**
**(Date not fixed) (Montreal).—Canadian Medical Association.**
**(Date not fixed) (Rome).—International Exhibition of Social Hygiene.**
**(Date uncertain) (Turin).—International Exhibition of Industry and Labour.**

**In 1912:—**
**Spring (London).—Second Optical Convention.**
**July (?) (Cologne).—International Congress of Nurses.**
**September (Prague).—International Congress of Radiology and Medical Electrology.**
**September (Berlin).—Sixth International Congress of Obstetrics and Gynæcology.**
**,, Visit of German Medical Men to America.**
**Nov. 22nd–29th (Washington, D.C.).—Fifteenth Internationa Congress of Hygiene and Demography.**

**In 1913:—**
**(London).—Seventeenth International Congress of Medicine.**

(London).—Historical Medical Exhibition. (Organised by Mr. Henry S. Wellcome.)
(Dresden (?)).—International Conference on Cancer.
(Washington).—Congress of American Physicians and Surgeons.
August (Buffalo).—Fourth International Congress of School Hygiene.

In 1914:—
(Vienna).—Third International Congress for Professional Diseases.

In 1915:—
(London).—International Prison Congress.
(London).—Imperial Exhibition (?)

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic (2 P.M.) Hospitals operations are performed daily.

## EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.*

*Lectures, original articles, and reports should be written on one side of the paper only,* AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

*Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.*

*We cannot prescribe or recommend practitioners.*

*Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."*

*Letters relating to the publication, sale and advertising departments of* THE LANCET *should be addressed "To the Manager."*

*We cannot undertake to return MSS. not used.*

## MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

The Index and Title-page to Vol. II. of 1910 were given in THE LANCET of Dec. 31st, 1910.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1910 are now ready. Bound in cloth, gilt lettered, price 16*s.*, carriage extra.

Cases for binding the half-year's numbers are now ready Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

### TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

| FOR THE UNITED KINGDOM. | | TO THE COLONIES AND ABROAD. | |
|---|---|---|---|
| One Year ... ... ... | £1 1 0 | One Year ... ... ... | £1 6 0 |
| Six Months ... ... ... | 0 12 6 | Six Months ... ... ... | 0 14 0 |
| Three Months ... ... | 0 6 6 | Three Months ... ... | 0 7 0 |

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rate of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

### TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at these rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

# The Hunterian Oration
ON
# JOHN HUNTER AND HIS MUSEUM.

*Delivered at the Royal College of Surgeons of England on Feb. 14th, 1911,*

BY EDMUND OWEN, D.Sc. SHEFF., F.R.C.S. ENG.,
CONSULTING SURGEON TO ST. MARY'S HOSPITAL, LONDON.

MR. PRESIDENT,—The century lacks but two years of completion when Dr. Matthew Baillie and Sir Everard Home, John Hunter's executors, in their desire to show a lasting respect to his memory, provided for the delivery of an oration on Feb. 14th, his birthday. And although one should not now expect on these occasions to hear anything fresh concerning Hunter, still we come to the familiar subject as one goes to a favourite drama or turns to some well-loved book.

Adequately to deal with the work of this many-sided man, the orator should be of philosophic mind, and well instructed in the history of surgery, and he should have a profound knowledge of plants and animals—not only in health but also in disease. It being thus beyond my reach to touch more than the fringe of Hunter's scientific work, I shall content myself with speaking of him as a man, and as the founder of a museum which is without a rival in the world. Of some men it may be said, as St. Paul disparagingly remarked of himself, that they are "born out of due time." Some, indeed, so far in advance of it, that the intellectual seed which they laboriously sow produces but a sorry crop, or lies decaying in the soil. Hunter, however, was happy in the date of his birth. Had it been delayed by, let us say, a century and a half, so that at the present time he would be approaching what the poet calls the "midway of the journey of life," he could not have attained the commanding position which, as it was, he occupied in so many branches of science. And had his birth been thus delayed, would he have chosen the philosopher's path which leads to the Temple of Wisdom? Would he have worked in the field which proved so attractive to Darwin, or in that to which Pasteur devoted his great mind? Would he have developed into a pathologist of world-wide reputation—like Billroth; would he have contented himself with being the foremost surgeon of his day, or would his thirst for collecting have triumphed over everything else? He could not filled each part. I am inclined to think that he would have given up everything in order to devote himself to biology.

John Hunter was the youngest of ten children, most of whom died early. It may have been on this account that his mother spoilt him—though *spoilt*, in this case, can hardly be the proper word. At any rate, he was allowed to have things very much his own way, his mother making him her Benjamin. It is good for no man to have things too much his own way at any time of life—least of all, at the beginning. And it might have been better for Hunter if his mother, instead of constantly giving way to him, had helped him in early life to obtain a command over his temper. For our hero was apt to be overbearing in his dealings with others, and intolerant when his wishes were thwarted. And this is made painfully evident as we come to deal with the closing years of his life. When he was about 17 he went to stay with his brother-in-law, a cabinet-maker at Glasgow, and, being very proud of the skill with which he could use his hands, he delighted to help in the workshop. And so the statement has become current that Hunter began life as a joiner, which is very far from fact.

It is apt to be set forth in the life-history of any person who has made for himself a high position in the world of science, literature, or art, that from early childhood he was seen to be in possession of unusual talent in that direction. Thus, for instance, Cimabue showed first proof of his great gift by making remarkable sketches upon his lesson-books, and it is related that certain popular preachers used to give displays of talent by fervid outbursts of oratory in the nursery or school-room—which, to the common type of man, might seem out of place or even unwholesome.

But so it was not with Hunter. He was quite an ordinary boy. To use the words of his biographer, "having little taste for books, he preferred in engaging in country sports to studying those elementary branches of knowledge which are best acquired in youth." In dwelling upon the story of his life it is a pleasure to meet with such an estimate of his character, for it supplies the needful human touch. At the time that John Hunter was getting out of his teens, his elder brother, William, was conducting with great success a private medical school in Windmill-street, Haymarket. He was a man of unrivalled talent, and though he was not connected with any hospital, had established a great reputation for himself as a teacher of anatomy and surgery. John was much interested in, and his imagination was set on fire by, the accounts which he heard of his brother, and, as has so often been the case with self-reliant and enterprising young Scotchmen, he also desired to travel along that broad and pleasant road which leads from the stern country of his birth to the Mother city of the Empire. So he wrote to William asking that he might be taken as an assistant in his dissecting-room. A favourable reply having been received, John left Scotland on horseback for London in September, 1747. Up to that time he had been looked upon as an idler. Not infrequently it happens that a boy who has not yet been put to the work for which Nature intended him, has been thus regarded, till, by a happy turn of the wheel of Fortune, he finds the occupation for which he was fitted. On arriving in London, John was at once put to work upon a dissection which was wanted for his brother's October lectures. This he did with such skill that he at once gained the entire confidence of his brother. William had been afraid that John might turn out but an idle apprentice. And though he stuck closely to his work in the dissecting-room and at the hospital, he lived outside of them a somewhat free and reckless life. Like an ordinary, human, young man, "Jack Hunter," as he was called, liked to shake off restraint at times—and he shook it off very thoroughly.

## CHESELDEN AND POTT.

It is a proof, if proof were needed, of the warm interest which William Hunter took in the shaping of his brother's career, that he obtained for him the practical teaching and the friendship of the illustrious Cheselden, of St. Thomas's Hospital, one of the greatest of English surgeons. He it was who invented the operation of lateral lithotomy; and when French surgeons came over to learn his art, they saw him operate on 27 patients for stone in the bladder in succession without a loss. And this, be it remembered, when stones, left uninterfered with, grew to enormous size, and when operations had not yet been made easy for the surgeon by the help of chloroform, nor safe for the patient by the adoption of methods of cleanliness. Richardson's portrait of Cheselden, which you see before you, shows him as a cheery-looking individual who might never have known an anxious moment. History tells, however, that he was of such delicate fibre, that whenever he had to perform a serious operation he felt sick at the thought of the pain which he was about to inflict. And, as he was constantly operating, it must needs be that his mind was much troubled. He was 60 years old when John Hunter was brought to him—a worthy pupil for so great a master. Four years later he died from apoplexy, a not uncommon cause of death of members of his profession—the result of high arterial tension brought on by ceaseless work. There is no eight-hours days for the medical man; he cannot reckon on Saturday as a half-holiday, nor Sunday as a day of rest. It is this continuity of work, this never-ending strain of tissues, which brings about the early loosing of the silver cord, the breaking of the golden bowl. Being thus compelled to look elsewhere for instruction, Hunter became a pupil of Percivall Pott at St. Bartholomew's Hospital. A better choice could not have been made.

On the left of Hunter you see the portrait of Pott, by Romney, whom Reynolds disparagingly alluded to as "the man in Cavendish-square"—Romney, whose delicate brush lingered so lovingly over the captivating features of Nelson's Lady Hamilton. These three pictures have, by leave of the President, been brought down from our Council Room, where for many years they have hung side by side and where, we trust, in spite of all changes which may take place in the social and educational life of this country, they may continue happily to remain till Time shall be no more. At the

present day portraits of women by Romney are chiefly sought after, but I think that I would as willingly possess his picture of Pott as any that he painted. Even the most successful portrait painter cannot always choose his subjects, but when Romney had Pott seated before him he must surely have been satisfied, for truly his is a beautiful face! Those who can read a man's character in his features will form the opinion that Pott was a true English gentleman. And their conclusion will be right. His devotion to his mother was romantic and intense; his kindness of heart was proverbial, and at one time he had three needy surgeons living under his hospitable roof. He was a man of high character and blameless life. Shortly after his death his friend, Sir James Earle, collected his writings and published them, together with a short account of Pott and of his work. He said that the labours of the greatest part of his life were without relaxation, but that in his later years he took things more easily, "gathering," as Pott had expressed it, "some of the fruit of the garden which he had planted as he went along."

Though, after Pott's death, Hunter was by far the greatest surgeon of the time, still he seemed to practise his art chiefly to earn money for making additions to his museum. He greatly disliked being called away from the museum. "Well," said he, on one occasion, when he was summoned to see a patient, "I must go and earn this damned guinea, or I shall be sure to want it to-morrow." Ottley, his biographer, apologises for the strength of Hunter's language, and tells us that he has generally omitted the swear-words, as "the objections to introducing them appeared to outweigh any advantage that such verbal exactness could afford." Perhaps he was right; but I confess that I would have preferred Hunter's unpolished expressions just as they came from the mint of his strong brain. Moreover, one almost expects to hear such words echoing from the days when men wore velvet coats and silk stockings, and were accustomed to say just what they thought—and to say it clearly and forcibly. True it is that at this time Bob Acres remarked that the best terms grow obsolete, and that damns had had their day. But Sheridan's poetic imagination seemingly led him to anticipate.

Hunter's unfriendly biographer Jesse Foot wrote: "John could never talk of his injuries, but would get rid of the passions they provoked in him by the bitterest utterings of swearing—Sterne's Dr. Slop could not have been a match for him." It was pure spite that made Foot compare Hunter with that old-fashioned Yorkshire apothecary, who, we know, was unusually free in his speech. When, as you may remember, Dr. Slop cut his thumb in trying to loosen the string which Obadiah had so tightly knotted around that green baize bag, Sterne says, "It would have done your heart good, and cured you, Sir, for ever, of the vile sin of swearing to have heard him." But I am indignant at Foot comparing John Hunter with Dr. Slop! My opinion is that he was jealous of the great reputation which Hunter had obtained in a class of practice in which he, Foot, was specially interested.

### HUNTER AND JENNER.

It would be impossible to give even a short account of the life of Hunter without speaking of the close friendship which existed between him and one of his former pupils, a doctor in general practice upon the Gloucestershire bank of the river Severn, Edward Jenner—one of England's greatest men. His discovery that the passing of the harmless germs of cow-pox through the blood renders a person secure against small-pox was not revealed until after Hunter's death. But we may permit ourselves to imagine the pleasure with which he would have regarded the philosophic bearings of Jenner's investigations, and the delight with which he would have hailed their conclusion. But what would he have thought, could he have foreseen that his friend's glorious discovery would at length be made a shuttlecock of political agitators, and that the cause of vaccination in the country of its birth should be so grievously neglected, that its compulsory adoption became a farce? The day of reckoning will surely arrive: England is sowing the wind, and she will not fail to reap the whirlwind. But, unfortunately, when the inevitable outbreak of small-pox takes place, among its victims will also be the ignorant and helpless.

Letter-writing was a far more important business 140 years ago than it is now; the art has been killed by the penny post. When Hunter was corresponding with his friend the postage of each letter cost at least 4*d*., which is equivalent to about 8*d*. at the present day. Hunter's letters to Jenner are delightful; and it is a great pity that we cannot have Jenner's in reply. In every letter Hunter is urging his friend to find material for his museum—fish, flesh, fowl—anything that has life, or that ever had it. And he was willing and anxious to pay for it. "You see," said he, "I am very greedy. Be sure you keep an account of all out-goings."

As a kind of set-off to what Jenner did for the museum, Hunter was more than ready with advice and help to his distant friend when surgical patients caused anxiety in his practice. Now, in the winter of 1776 a particular case was giving Jenner much anxiety. It was that of a boy with an open wound in his skull, from which a mushroom-like growth was bulging. Jenner did not know how to cure the boy; if he had lived at the present day he would have been no wiser. So he begged Hunter to advise him. "I don't know any one I would as soon write to as to you," replied Hunter, and he then thanked him for certain things which he had sent for his museum, and remarked that he had not yet received the cuckoo's nest. He would have had to wait a long while for a nest of that out-and-out socialist of the feathered tribe, who leaves to others the responsibility of the housing, the rearing, the feeding, and the education of his offspring!

> Now for your patient. I believe the best thing you can do is to do little. I would not touch the fungus with a caustic for fear the brain should be near. Keep your patient rather low and quiet.

And what excellent advice it was! Could the Council of the College of Surgeons of to-day suggest anything better? But Jenner was not satisfied, for in a little while he was again questioning about the boy. And Hunter, with his museum in his thoughts, wrote in reply:—

> Send everything you can get, either animals, vegetable, or mineral, and the compound of the two, either animal or vegetable mineralised. I would have you do nothing with the boy but dress him superficially; these funguses will die and be damned to them, and drop off. Have you large trees, of different kinds, that you can make free with? If you have, I will put you upon a set of experiments with regard to the heat of vegetables. Have you any eaves where bats go to at night?

And so on. Still Jenner was not satisfied, and in less than a fortnight he was again writing about this worrying case. Hunter replied:—

> I would advise you not to meddle with it. Be quiet; and think yourself well off that the boy is not dead. You do not mention a word about bats. Have you got the bones yet of a large porpoise? I wish you had. Is ever the salmon-spawn seen after she has parted with it? If it is, I wish you could get some. I want to examine the spawn of fish in the progress of the formation of the young one.

In the next letter Hunter is asking again about the salmon-spawn, and is suggesting that Jenner should undertake some work upon the sex question of eels. He appealingly ends the letter by asking, "Cannot you get me a large porpoise for love or money?"

I am tempted to keep you one moment more over these letters because, being written to his dearest friend, they show the inmost working of his mind, and they plainly tell us that the one thought of his life was his museum:—

> Dear Jenner, I received your salmon, and very fresh, and just examined enough to want another. I will take a cock-salmon when you please. If you catch any bats, let me have some of them. Did I write to you some time ago about cuckoos? I have forgot; if I did not, I must give you a long order.

He does not ask about that boy; nor, so far as one knows, does Jenner trouble him any further in the matter.

At about this time Jenner had fallen deeply in love, and just when things seemed to be leading up to a happy marriage black disappointment threw over them his pall. Hunter, ignorant of what was going on in Gloucestershire, continued to write for various objects for the museum. But he received no response. Then he heard a rumour of Jenner being married, so wrote to congratulate him, sandwiching his congratulations between remarks on hedgehogs and fossils. On the broken-hearted Jenner replying that not only was he not married, but that, unhappily, all was over between the lady and himself, his friend replied:—

> I own I was at a loss to account for your silence, and I was sorry at the cause. I can easily conceive how you must feel. But let her go, and never mind her. I shall employ you with hedgehogs.

And then he gave him a list of investigations which he was to make with these animals. His museum was always in the front of his mind. Whether he was writing about a patient or about his own serious breakdown, or about his friend's

marriage or his grievous disappointment, he was ever thinking what he could do to render his museum more complete, and so to increase its value as an educational institution. Another great reason for his anxiety to make it more perfect was, as his brother-in-law tells us, that it might sell the better after his death, for, having spent almost all his fortune over it, he had been able to make scarcely any other provision for his family; "his expenses had always exceeded his income."

### HUNTER'S DAILY LIFE.

Hunter was at work in his museum from dawn till breakfast; and he was in his consulting-room or in his carriage, and visiting his hospital or his private patients, from breakfast till dinner—which he took, according to the custom of the day, at 4 o'clock. After dinner he went to sleep for an hour, and then sat down to write letters and essays, to work up clinical records, or to describe preparations for his museum. At midnight the butler brought him in a fresh lamp, by the light of which he continued to work on till one or two in the morning, or even later in winter. So that, including the nap which he had after dinner, he was apt to get but four or five hours' sleep out of the 24. We are plainly told that he had no home amusements, and that he took his greatest pleasure amongst the wild animals which he kept in the garden of his house in Earl's Court where he slept, and where, with his family, he spent the greater part of his time in the autumn months. What a life to live! Which of us would accept it, even to be, as Hunter is, immortal? But Nature, ever jealous, could not pardon even him, her devout and loving disciple, for so long and complete a neglect of her unwritten laws. As far as one can make out, he took no bodily exercise, and sought little mental relaxation. The bow was never unstrung. As one looks back upon this unresting student of Nature one can scarcely help regretting that he had no experience of those two amusements over which men and women of to-day are apt to waste so large an amount of time—golf and bridge. As recreations for intellectual workers, what more suitable; as life's chief occupations, what more pitiable!

There is little to suggest that outside of the science and practice of his profession Hunter found much to interest him. The letters which he wrote and received, or, at any rate, those of them which have been preserved and published, make no allusion to sport or pastime; and there is no mention of foreign travel, that delightful relaxation for a busy man with no special interest in the pleasures of country life. Indeed, Hunter's one and only happiness was in intellectual work, and especially in that which concerned his museum. Every medical man should make for himself interests outside of his profession to which he can devote himself in the odd times in which he can escape from the anxieties of his occupation. Intemperance in work is well-nigh as harmful as intemperance in eating or in drinking. In the absence of outside interests a medical man is truly to be pitied. When, with advancing years, he unwillingly retires from the contest, if there is nothing better for him to do than to look wistfully backwards or sorrowfully forwards the evening of his life must, indeed, be dark and miserable. But happily there was no evening to Hunter's life; he died before the lengthening shadows fell across his path.

### HUNTER AND THE COLLEGE OF SURGEONS.

The records of our corporation show that at a Court of Examiners held in July, 1768, John Hunter was examined for and received his diploma. Amongst his examiners was his former master, Percivall Pott. Hunter was then 40 years old. Already we have heard of him in connexion with the Corporation in the minutes of the Court of Assistants of July, 1753, where it is stated that Pott and Hunter were elected Masters of Anatomy.

In accordance with the by-laws, the Court had to make six anatomical appointments each July—two Stewards of Anatomy, two Wardens of Anatomy, and two Masters. The business of the stewards was to prepare the subjects for the lectures; of the wardens, to act as demonstrators; and of the masters, to give the lectures. It was the duty of the Court of Assistants to choose these officers from amongst the members of the Corporation. The appointments were for one year, and if a member thus chosen said that he wished to be excused from holding the office he was fined "twenty-one pounds lawful money," for so it was nominated in the Bond. The plea of incompetence for the task, or of illness, was not taken as an excuse—the work had to be done or the fine had to be paid. Fines of all sorts were, indeed, the great source of income to our Corporation in those days. In the minutes of the Court of Assistants of Oct. 5th, 1786, it is recorded that Mr. John Hunter had presented to the Corporation two volumes of his "Natural History of the Human Teeth," and a copy of his "Treatise on the Venereal Disease," and in accepting them the Court passed him a vote of thanks. When, in 1745, an Act of Parliament enabled the Surgeons to free themselves from the Barbers, they became a corporation under the Government of a Master and a Court of Assistants—21 in all. Shortly afterwards they built for themselves a Hall in the Old Bailey. And early in 1789, in order to fill the vacancy caused by the death of Pott, Hunter was elected a Member of the Court—which corresponds with the present Council of the College. Appointment was for life, and as Hunter died in 1793 he was a Member of the Court for four and a half years. Foot says that during this time he attended only one meeting. That, however, is a mis-statement—"calculated and frigid."

The Court met quarterly, and it had now and then, in addition, a special meeting. Hunter was elected in February, 1789, and in the following April he came to be admitted, taking the oath and paying the fine of £21. There were three other meetings in the year of his election, at each of which he was present; and there were five in 1790, from only one of which he was absent. There were six meetings in 1791, but he attended only two of them; in 1792 there were six meetings, two of which he attended; and in 1793, in the October of which year he died, he was present only once. Altogether he attended 14 meetings out of 26, which is, indeed, a very poor record. In his last two years he was absent from eight meetings out of eleven, and my explanation for his increasing lack of interest in the affairs of the Court of Assistants is that he got on badly with his fellows, and especially with three highly placed Members who came from his own hospital—Gunning, Walker, and Hawkins. Though there may not have been open enmity between him and them at that time, they certainly were on unfriendly terms. Indeed, Ottley tells us that they were frequently in collision. At a meeting on Nov. 7th, 1793, as recorded in the minutes, "The Master reported that since the last Court of Assistants Mr. John Hunter, a Member of the Court, had departed this life, and declared a vacancy in pursuance of such his death." Nothing further is noted: no resolution of regret or of condolence appears to have been passed. And Dr. Peachey, who has kindly examined for me the minute-books of St. George's Hospital, says that he can find in them nothing more than the bare notification of his death.

There is no denying it, Hunter did not agree with his fellow practitioners. Foot affirms that he hated his equals in the profession, and it was probably true, for Ottley writes that his manner to them was "blunt and overbearing." As Surgeon-General to the Army he had great patronage, and he was in the habit of refusing recommendations which other surgeons made for vacant military appointments, and of giving pretty nearly everything to his own pupils and associates. This made him highly popular amongst his friends, but it was gall and wormwood to the other hospital surgeons, many of whom were upon the Court of Assistants. If he could have foreseen that this College was eventually to have the guardianship of his museum things might have been different. When, six years after his death, Parliament purchased his museum for the nation, it was offered first to the Royal College of Physicians, and it is only because of their declining to accept its custody that Government entrusted it to our keeping. But had the trust been accepted by the Sister College, she would have found a medical and a philosophic side to Hunter's work which would have justified her in giving him an honoured place by the side of her Harvey and her Sydenham. Fortune, however, was not blind when she settled that the world-famed collection, with its countless associations, should be handed over to this College. And justly may it be claimed that nowhere else could the conditions of the trust have been more faithfully or devotedly observed.

### HUNTER'S ILLNESS.

It has been truly said that a man is as old as his arteries, and looked at from this point of view, though Hunter's age at his death was under 65, he had for many years been far older than that, for he was the subject of advanced arterial

disease. It is impossible to say at what time the disease began; it comes on so slowly that for a long while there may be nothing to call attention to its presence. But in the spring of 1773 he had an alarming attack of spasm, in which for about three-quarters of an hour his heart stopped beating; it was apparently caused by mental worry. Four years later he had a still more distressing attack, which was also brought on by anxiety. And this time he suffered from a continuous giddiness which prevented him raising his head. The mental shock so affected his feeble heart that it was unable to pump blood to the brain through the narrowed vessels. But though this must have been felt by him to be a warning, he evidently did not allow it to cause him alarm. This is the way in which he refers to it in the middle of a letter which he wrote to Jenner a few weeks afterwards:—

> I had the pleasure of seeing your brother, but only for a time. I received the bird; I am not acquainted with it. Send me some more if you can get them readily. Not two hours after I saw your brother I was taken ill with a swimming in my head, and could not raise it off the pillow for ten days. It is not yet perfectly recovered. Have you begun the eels? No porpoises. No salmon-spawn before it is hatched. You see I am very greedy.

This letter is especially interesting in the light of those other letters. In them, as you remember, when Jenner was anxiously asking how he should deal with that boy with the damaged head, Hunter could, apparently, think of little but his museum. And here, when Hunter is telling Jenner how Death had been giving what was, as a fact, his second loud knock, he refers to it merely as an incident, between the welcoming of a rare bird to the museum and a reminder that Jenner has not yet told him of the result of his researches concerning the eels. What a mental picture it offers—Hunter discussing the sex problem in eels whilst Death is waiting at the door!

But though Hunter gave little heed to his illness his doctors insisted on his going for a complete rest to Bath. And as soon as he was settled there Jenner went over to see him—a journey of about 20 miles—and was alarmed by his altered appearance. He said nothing to Hunter, however, but he wrote to his London physician, giving it as his opinion that all the trouble was due to imperfect nourishment of the heart-muscle the result of arterial disease. And Jenner was right. After remaining three months at Bath, though by no means recovered, Hunter went back to London and set to work at his museum and his practice as if nothing had happened.

In 1785—that is, eight years after his last attack, and as many before his death—his disease caused him increasing distress, and especially so when he was angry; and as he grew older his temper did not improve. He would fly into a passion for very little cause, upon which an attack would come on, leaving him exhausted and miserable. It is a sad story—the man of giant mind such as the world rarely produces, worn out with incessant work and insufficient rest, torn to pieces by an ungovernable temper, and left, at shortening intervals, faint and helpless! It was all very well to call his complaint "flying gout"—whatever that may mean—it was something far more serious. Once more he visited Bath—but with little success. Indeed, he was in such a poor state of health that any other man in his position would have given up work altogether and retired into private life. Dante reminds us that there comes the time to each one of us when, like a mariner approaching the port, he should lower the sails and gather in the ropes.[1] But Hunter refused to see that this time had come to him. Though he knew that his days were uncertain, he felt that life without work would be intolerable. Above all things, his museum must be attended to. So he came back to London and (November, 1785) again put on harness.

Having thus brought you to look upon Hunter as a man bankrupt in bodily health, which, indeed, he was, I wish you to see, by contrast, that his mind was in full vigour, for it was at this time that he thought out and carried into execution a new operation for the cure of aneurysm—a piece of work which alone would have sufficed to place him for ever in a niche in the Temple of Fame. Time will not allow me to do more than merely refer to the great advance which this measure effected in the march of surgery. But I think it right to take this occasion of saying that its conception was the direct result of an experiment carried out on a living animal. And if no other piece of useful knowledge than this had ever been established by such method of experiment, it alone would abundantly justify the resort of the man of science to the use of what is commonly spoken of, and too often spitefully spoken of, as vivisection.

[1] . . . quella parte
Di mia età, dove ciascun dovrebbe
Calar le vele e raccoglier le sarte.

### HIS ILL-HEALTH ACCOUNTED FOR.

One cannot deal satisfactorily with the question of Hunter's ill health unless one keeps in view the fact that, as the result of what must be called a "vivisection" experiment upon himself, he became the subject of constitutional syphilis. Though he had abundant opportunity of studying the progress and the effects of syphilis in patients coming to him for treatment after accidental infection, he desired to watch its course in a less impersonal manner. So he calmly dipped a lancet in venereal matter and inoculated himself with it. The experiment was a highly risky one, and it proved disastrous. Medical men and medical students have in all times been willing to offer themselves upon the altar of Science in the hope of solving some pathological problem, or of helping onward some scheme of treatment which might prove useful to their fellow creatures. Hunter's trial upon himself by no means stands alone.

Hunter was then in his fortieth year. He well knew the seriousness of the constitutional disease with which he had infected himself, and whilst watching its progress he found that he could check it by a certain line of treatment; but he writes that as soon as he found himself thus getting better he stopped the treatment, "for the intention was not to cure the disease completely at present." In due course his throat became ulcerated, and, having again adopted enough of the treatment to cause the ulcer to "skin over," he once more ceased it, as he did not then wish to destroy the poison, "but to observe what parts it would next affect." In three months copper-coloured blotches broke out on the skin, and ulceration once more attacked the throat. At a later date, when he thought that he had learnt all that was possible from his experiments, he set to work to cure himself. From the date of his inoculation to the completion of the treatment of the disease was about three years. He was apparently satisfied that the knowledge which he had thus obtained was sufficient reward for the inconveniences which he had undergone, but no medical man, looking back, would share with him that feeling of satisfaction. The price paid was far too heavy!

There can be little doubt that the progressive arterial degeneration of which he was the subject was greatly, if not altogether, due to that self-inflicted disease from the effects of which he never actually recovered. Not only did it render him feeble in body, but it also disturbed the balance of his mind and made him increasingly restless and irritable. Thus to think upon Hunter and his illness is to enable one to look upon his vast achievements with increased respect, and to regard his failings with unstinted sympathy. The longer one lives the more fully does one realise the truth of the French proverb which tells us that to understand all is to forgive all!

### HUNTER, PASTEUR, AND LISTER.

Just now, when speaking of the friendship which existed between Hunter and Jenner, I referred to the delight with which Hunter would have looked upon the discovery of vaccination as an almost certain protection against small-pox, which his earlier death prevented him witnessing. And as the shade of Hunter wandered through the Elysian fields, he must have offered a warm welcome to another kindred spirit of the commonwealth of Science, and one of its brightest ornaments—Pasteur—who joined him after a hundred years. With what pleasure would these men discuss the many subjects which lay within the space in which the work of the physiologist overlapped that of the physicist! With what interest Hunter, one of the earliest friends of our Royal Veterinary College, would listen to Pasteur's account of the outbreak of the cattle-plague in France, of the pestilence amongst the silk-worms, and of the diseases of wine and of vinegar, all of which he had made to disappear by the touch of his magic wand; and with what approval would he follow Pasteur's account of the way in which he worked out his theories in connexion with that terrible disease, hydrophobia, and established their truth by experimentation on the animals themselves. What a group is it—Hunter, Jenner, and Pasteur—Jenner, Hunter's

friend in the flesh, and Pasteur in the spirit! And having thus spoken of the spiritual association of Hunter with Pasteur, it will be but a short step to connect Hunter's ideas with those of our Lister. For the range of his mental work in surgery (as was first pointed out to me by Mr. Dent) did actually touch that of Lister. Hunter is lecturing to his pupils upon hectic fever, which we now know to be the result of slow blood poisoning, and these are his words:—

> We have as yet, I am afraid, no cure for this. I believe the cure consists in the removal of the cause—namely, the local disease. Strengtheners and antiseptics are recommended. Strengtheners are proposed on account of the debility which has evidently taken place, and antiseptics, from the idea of absorbed pus giving the blood a tendency to putrefaction.

Here, then, is Hunter, a hundred years before Lister, talking about pus and putrefaction, and ascribing hectic fever to blood poisoning, just as Lister would do, and, moreover, saying that the disease should be treated by *antiseptics*—using Lister's favourite word. Hunter had thought it out for himself, turning the rough idea over in his philosophic mind until he had it ready for presentation to his students.

Look at him in Reynolds's magnificent picture. He is seated at a table with an open book beside him with drawings of skulls; there are also on the table an anatomical preparation and two closed volumes. But evidently his thought is not with *them*. His face shows that he is deep in meditation, and that his thought is far away—a hundred years forward, as likely as not. And if so, may it not be that at that very moment it is on the fringe of the work of Pasteur and Lister? At any rate, at one time or another he was within touch of Lister's immortal discovery. And he could have reached it without the help of a microscope. He might, like Pasteur and Lister, have put the fresh-boiled broth into a sterile vessel; and, having shielded it from dust, kept it sweet for weeks. Then, carrying out the same idea with a clean surgical wound and treating it with "antiseptics," he would there also have secured the wished-for result—its prompt healing. By the broth losing its clear appearance and its wholesome smell, as by the wound becoming swollen, offensive, and bathed in pus—the result of their having been infected—he would have been led to see and grasp the great truth, and then would have worked out the simple and beautiful antiseptic theory as we practise it to-day. But in a mind so crowded with ideas that it was, as he said, "like a beehive," it might not have taken much to turn aside that current of his thoughts. So that, if, by chance, a vision of the antiseptic method was occupying his thought when Reynolds caught that charming expression, a casual remark from the painter might easily have caused it to vanish into thin air.

The portrait was painted in May, 1785, three months after Hunter's fifty-seventh birthday, but it shows him looking a good deal older than that. Indeed, Everard Home says that, after his serious attack, "he gave the idea of having grown much older than could be accounted for from the number of years which had elapsed." The picture was hung in the exhibition of the Royal Academy of the following year, as the "Portrait of a Gentleman." But in the course of time, on account of the nature of the pigments used, it darkened and cracked and threatened to go to ruin. At last, when its condition seemed well-nigh hopeless, it was restored by an expert named Farrar, who in the course of his remarkably successful work, removed the paint from the old canvas and re-applied it upon a new one. The story of the painting of the picture is well known—Reynolds found Hunter a bad sitter. Probably Hunter did not like being under control, and became as difficult to pose as a restless boy at a photographer's. And so it came about that, though the picture was far advanced, the artist was not satisfied with it. One day however, Hunter fell into a waking dream as he sat, and "Reynolds, without a word, turned the canvas upside down, made a fresh sketch, with the head between the legs of the former figure," and obtained the result which you see. Much the same thing happened when Mrs. Siddons was sitting to Reynolds as the Tragic Muse. He had already sketched the head and face, and when he had turned away from the easel to mix some colour Mrs. Siddons changed her position in order to examine some picture hanging on the wall. Reynolds was so pleased with this natural pose that he begged her not to move, and he then painted her as she is seen in the glorious picture at Grosvenor House.

In a lecture on Sleep, Hunter says: "It is even possible to dream when awake; it is only necessary for the thinking power to take possession of the mind, and proceed with an action with which the present sensation has nothing to do. Now, whenever the body loses the consciousness of its own existence, it may be called a waking dream, and this is often the case when people are in deep thought." In this great picture Hunter is truly in a waking dream; and no one will venture to contest the point if I suggest that he is dreaming of putrefaction, of suppuration, and of the antiseptic system which was to come! The picture was presented to the College by Hunter's son in February, 1821, with the accompanying letter, addressed to the secretary:—

> SIR,—I have no doubt that the placing the portrait of my dear Father, the late John Hunter, Surgeon, in his Collection will meet with the wishes of the College of Surgeons, and that the gift of the above portrait will be acceptable to them. I do not think it can be more appropriately situated or more worthily disposed of. I therefore beg leave to make them the offer, and to add that I shall think myself honoured by their acceptance of it. I am, Sir, your obedient servant,
>
> JOHN BANKS HUNTER.

## HUNTER AND ST. GEORGE'S HOSPITAL.

Hunter's colleagues at St. George's Hospital regarded him as a dreamer, and refused to see that his physiological studies could have any useful influence on the work of the practical surgeon; whilst Hunter, from his high standpoint, looked down upon them, and treated them with scant respect. Thus there was between him and them an entire absence of that good feeling which it should be the duty of every member of a hospital staff to cultivate, not only for his own happiness, but in the interests also of the hospital, the students, and even of the patients.

At the beginning of 1792, when Hawkins retired from the hospital, Hunter did his utmost to secure the election of Mrs. Hunter's brother, Everard Home, to the vacant post. Gunning and Walker, however, fought against him to get in Thomas Keate, who proved successful by 134 votes against 102 cast for Home. "This," says Ottley, "could scarcely fail to heighten existing animosities." Those two words, "existing animosities" give clear proof that Hunter greatly disliked Gunning and Walker, and I am going to assume that Hawkins (into whose vacancy at St. George's Hospital Keate had been elected) sided with them against Hunter.

Those of us who have had experience of the wretched system of election to a hospital staff by canvass and open vote can understand the bitterness caused by the Keate-Home contest—a bitterness made all the greater by the fact that it was somewhat of a family affair. As a result of his defeat, the iron entered deeply into Hunter's soul, and he turned round on his colleagues and declared that he would no longer agree to the division with them of the surgical pupils' fees, and that for the future he meant to keep for himself all moneys paid by students who entered under his name. He claimed that he did this in order to stimulate the other surgeons to do better for the students than they had done in the past, as, in his opinion, their neglect had brought disgrace upon the hospital. Gunning, Walker, and Keate replied; and, whilst admitting that more pupils entered under him than under them, claimed that they did so from a knowledge of the fact that he would be likely to find army appointments for them later on. And they set forth this unanswerable objection to his scheme, that if a pupil entered the hospital for the practice of one surgeon, he would be unable to watch the work of the other. To have agreed would have been to admit that they had actually been blameworthy, but they said that they would like to have the matter referred to the governors of the hospital. Hunter replied that he accepted their proposal and that he would meet it "fairly and very willingly." And before the meeting he sent a long printed document to each governor setting forth his case.

Hunter's scheme, which was conceived in a moment of wrath, was an impossible one, and the governors rightly gave their decision against it. And after this, in order to promote the smoother working of affairs at the hospital, a committee was appointed to draw up a code of regulations, amongst which was one forbidding the admission of pupils who had not already received some medical instruction. The effect of this would be to shut out young fellow-countrymen of Hunter who were attracted to the hospital by his reputation and success. Indeed, soon after the adoption of the code, two Scottish youths, without any knowledge of medical work, applied to Hunter to be received as his pupils at the hospital. He told them of the new law, but promised to try to obtain permission

for them at the meeting of the board which was to be held on Oct. 16th.

Hunter's position at that time was not a happy one. He had quarrelled with his colleagues and had twice been beaten by them in contests before the governors of the hospital, and he was now going to engage in another fight with them. Worse than all, he was the subject of a disease which gave him distress whenever he was excited or angry. Something told him that disaster was close at hand. As he was addressing the board at St. George's Hospital, a member of it, possibly Gunning, gave him a flat contradiction, on which he stopped speaking, hurried into an adjoining room, and fell lifeless in the arms of one of the physicians. A more dramatic ending to a strenuous life could not be imagined; and doubtless it called to the mind of many people the sudden heart failure of Chatham when he was addressing the House of Lords a few years before. But between Chatham's seizure and his death there was a delay of some weeks, whilst Hunter's death followed his attack with awful suddenness, as when the deafening thunder rolls upon the vivid lightning-flash.

If, as I claimed just now, Hunter was happy in the time of his birth, equally so was he in that of his death. He was then in his 65th year—an age at which he could not expect surgical practice to be increasing. His heart disease was steadily getting worse, and he himself more irritable; and though he was still full of energy, he was wanting in strength. His museum, daily growing larger, was making heavier demands upon his purse, and he had already spent so much upon it that he had but little private means. Surely Death came to him as a friend, as, indeed, he comes to most of us, if only he does not too long delay his coming.

On examination after death, it was found that his heart was wasted and small, its muscular tissue being "pale, and loose in its texture." The arteries of the brain and of other parts were thick and rigid. Commonly it happens that when a man's arteries are diseased, the muscular wall of the heart grows stronger and more massive in its effort to pump blood through the resisting tubes. But as Hunter had not been in the habit of making vigorous calls upon his heart by physical labour, his heart possessed no reserve of force, and readily gave up the unequal struggle. In an ordinarily healthy man, taking a fair amount of exercise, if the heart is called upon to do extra work—as in the case of valvular or arterial disease—its muscle becomes thick and strong, like that of the blacksmith's arm, but the heart of Hunter actually shrank from the task. And, just as Jenner had foretold 16 years before (after that visit of Hunter to Bath), the arteries supplying its muscular tissues were converted into bony canals. The aorta was dilated, and all the valves of the heart were out of working order.

There are few great men the details of whose life are so well known as are those of John Hunter's. His history is an open book which anyone may read. And though we fully recognise the grandeur of his intellect, we also see his weaknesses and admit his faults. No part of his industrious life is hidden behind a curtain which the historian feels it better to leave undrawn. We are told almost every detail; we know the full story of his death, and we have a sufficient account of the result of the examination of his body after death to enable us clearly to understand its cause. And as we learn of the gross changes which were revealed in his arteries, the opinion grows stronger that they were to a large extent the result of those disastrous experiments which he made upon himself a quarter of a century before.

When reading the biography of a man one expects to find that as he advances in years the little faults of his earlier days disappear, and that his views, his interests, and his hopes become wider—that, in short, his character gradually takes on the richer tints of autumn. But so it was not with Hunter. The sunshine and the rain which had come into his life had had no mellowing effect upon him; the jealousies and the bitterness of his nature steadily became more marked. And from what one knows of the results of syphilitic degeneration of the blood-vessels, one would probably be right in ascribing the early coming on in him of old age, and the growing irritability of his temper, to the effects of that disease with which he so unwisely inoculated himself. This great high-priest of Nature ought, of course, to have been buried in Westminster Abbey; but no invitation was forthcoming. In those days Theology looked askance upon Science. So the body was enclosed in a coffin and quietly placed in the vaults of that church which stands between the Strand and Trafalgar-square, for, as Hunter lived in Leicester-square, St. Martin's-in-the-Fields was his parish church. And there it would probably have been to-day, but that in the beginning of 1859 a member of our profession, Mr. Frank Buckland, saw a notice in the *Times* to the effect that by an Order in Council the vaults of St. Martin's Church were to be bricked up. Believing that the body of Hunter was lying there, he visited the church, and found the following entry in the sexton's register concerning Hunter's funeral arrangements under the date of October 22, 1793—

> John Hunter, Esq., Leicester Square, No. 3 Vault.
> £6. 10. No candles; ½ past 4.

Buckland made it his care to find the coffin. On the door of Vault No. 3 being opened he saw, by the help of a bull's-eye lantern, that the vast space was stacked with coffins from floor to ceiling, in "most admired disorder." Some were lying east and west: some north and south: others were placed crosswise, and some were standing up on end. Every one of these had to be taken out so that the name-plates might be read. This was a long and gruesome business, as the coffins were heavy of oak and lead, and he and the men helping him spent 15 days over it. At last, when upwards of 200 coffins had been fruitlessly examined, there were only five left at the end of the vault; and as he could read the names on the three uppermost of these, he feared that his chance of reaching the object of his search was small. However, on one of the last two he had the satisfaction of finding the inscription:—

> John Hunter, Esq.,
> Died 16 October
> 1793
> Aged 64 years.

And above these words were engraved the arms of the Hunter family.

Thereupon the Council of this College approached the authorities at Westminster, and asked that the body might be granted tardy burial in the Abbey. The Dean, Dr. Trench, worthily replied: "We shall be proud to be the guardians there of the ashes of so great a man." The coffin, therefore, was brought to the Abbey, and on March 28th, 1859, in the midst of a crowd of illustrious persons, all that was mortal of John Hunter was laid in the earth of the north aisle, not far from the last resting place of Isaac Newton. And as the coffin was being lowered into the vault the organ pealed forth that magnificent chorus from Handel's Funeral Anthem—

> "His body is buried in peace; but his name liveth evermore:"

To you, Mr. President, and to me, as to others who are devout worshippers at the shrine of Hunter, there may appear little or nothing in this address which is worthy of attention. Still, it may be hoped that in its course some stray thought may have been set free—as when a flint strikes steel—which, falling upon the mental tinder of some younger man, may cause the springing up in him of a flame to illuminate his studious path and help him onward. Indeed, without the hope of some such effect resulting from a Hunterian oration, the pious intention of John Hunter's executors might well be allowed to sink into oblivion. And even for those of us whose thoughts should be directed to the lowering of the sails of their bark, and the gathering in of the ropes, there will still remain a place in the mental vision for the picture of a raw Scottish lad coming up to a great city in which he had but one friend, and, possessing nothing beyond the rudiments of an education, seeking his way to a position in the world of science and of art such as it is the lot of few to attain, and without any indebtedness to the goddess Fortune, reaching it by dint of industry, vigour, and determination.

---

KING'S COLLEGE HOSPITAL.—The annual court of the corporation will be held at Portugal-street, Lincoln's Inn, London, W.C., on Thursday, Feb. 23rd, at 5 o'clock, when a report of the receipts and disbursements of the past year and of the general state of the hospital will be presented and other special business will be transacted.

ABSTRACT OF

# The Lettsomian Lectures

ON

# OPERATIONS FOR STONE IN THE MALE BLADDER.

*Delivered before the Medical Society of London on Feb. 6th and 20th and March 6th, 1911,*

BY WILLIAM F. HASLAM, M.B. BIRM., F.R.C.S. ENG.,

SURGEON TO THE BIRMINGHAM GENERAL HOSPITAL.

## LECTURE I.

*Delivered on Feb. 6th.*

IT was known, said Mr. Haslam, that operations for the removal of vesical calculi had been performed for over 2000 years, and they were indebted to Celsus for a clear description of the method then adopted, which, with but little variation, kept the field for over 1500 years, and was at times practised as lately as 200 years ago. This operation seemed originally to have been regarded as beyond the scope of the practitioner of that lime, for they found that those who took the Hippocratic oath bound themselves not to perform this operation; the disciple, taking the oath, said, "I will not cut persons labouring under the stone, but will leave this to be done by men who are practitioners of this work." The operation was performed as follows. The fore- and middle fingers of the left hand were inserted, one after the other, into the anus, while the right hand was placed on the lower abdomen. The stone was then sought for by the fingers of the left hand in the rectum, assisted by those of the right hand, which pressed from above into the pelvis and kept the stone in front of the left fingers, so that these might press it from behind forwards against the neck of the bladder and perineum. Celsus was fully alive to the danger of dragging a large stone through a small incision, and he therefore recommended that "when the stone is too large to be extracted without laceration of the neck of the bladder it is to be broken." This was accomplished by fixing it with a hook and then striking it with a suitable iron instrument. With slight modifications the Celsian operation was in favour with some surgeons for over 200 years after 1524.

In spite of its many defects the Marian operation which followed found many ardent supporters; it was taken up and run as a special procedure by the Collots, the first of whom, Laurent Collot, was appointed to the position of court lithotomist in 1556 by Henry II. of France. The Collots were famous lithotomists for eight generations, but they kept their exact method of operating a secret. There were two statements as to how this became known—one that a book was found in the closet of the elder Collot, written in his old age, containing an authentic account of his operation; the other and more exciting version being that some surgeons bored through the ceiling of the operating theatre at La Charité in order to watch the great operator at work. They were rewarded for their trouble by seeing him do an operation which was only a slight modification of the Marian, which was well known to all those practising lithotomy. The operator was Jerome Collot who died in 1684. The Collots were strong supporters of dilatation; indeed, they considered that the whole secret in operating lay in the dexterous use of the dilators, and when the gorget was invented one of this family took upon himself to defend the dilator, which it was intended to replace. The gorget was not at first a cutting instrument, but merely a blunt wedge, a scoop of conical form, which, from the form of its beak, slipped easily along the groove of the staff, and by its wedge-like shape dilated the wound, and by the groove or hollow served as a conductor for the forceps. In studying the Marian operation it was noted that it was faultily conceived and so rough in its detail that the patient stood but a poor chance. The operators desired not to cut into the bladder, but to effect an entrance by dilatation. The incision was placed too far forwards and was in the perineum and did not extend into the ischio-rectal fossa, where there was more room for the passage of the stone. The urethra was opened through the bulbous portion, and as the surgeon was impressed by the idea that membranous parts should not be cut the membranous urethra, together with the prostate and neck of the bladder, were dilated, or rather torn open, by his instruments. The destruction of so great a length of the urethra—for by the time the operation was completed it amounted to this—led to the formation of a permanent fistula, if the patient escaped the ordeal with his life.

When Frère Jaques appeared in Paris in 1697 and exhibited to the profession his method of extracting the stone, there was a general feeling, not only among the profession, but among the public, that here, at any rate, was a method that, so far as extracting the stone was concerned, was less brutal and far quicker than the Marian operation, and that, whether the results were good or bad, the patient was spared the prolonged agonies of this procedure. The principle of the operation as performed by Jaques was to cut, and not to dilate, the deeper parts of the wound. He it was who showed that wounds of membranous parts were not mortal, and that Celsus was right when he said, "It is safer to cut than to dilate." By some he was regarded as one sent from Heaven to alleviate the sufferings of his fellow creatures. By his enemies—and he naturally had them—he was spoken of in different terms. He travelled over the provinces of France, assuming the name and character of a hermit or religious man, and he cut those who came to him with stone. He appeared to have extracted certificates from the friends of those on whom he operated, who were astonished at the dexterity with which he extracted the stone. He, however, had the sense not to wait until the time of cure arrived, but at once passed on to another district, leaving his patients to their fate, and many of them died. Frère Jaques's operation was done as follows:—

Having introduced a staff into the bladder, without a groove, he took a long knife with which he made an incision by the side of the left ischium, and cutting obliquely upwards he divided all the parts between the tuber ischii and the staff, which he allowed to remain in the bladder; he cut so freely upon the staff as to admit the finger into the bladder; along the finger he introduced an instrument which he called his conductor, as if to dilate the wound, and along the conductor he passed the forceps. Having introduced the forceps he withdrew the conductor; upon finding the stone he withdrew the staff also, and having seized the stone he drew it out.

Jaques operated in public at the hospitals, and so great was the desire of all to see him that sentries had to be placed at the gates to keep the mob back. Men from all parts came to see him operate, and they were greatly impressed with his boldness and rapidity, for it is stated that on one occasion he cut nine patients in three-quarters of an hour—a very remarkable performance when compared with the time taken in operating by the Marian. For a time all went well, and his enemies seemed unable to attack him with any success; but before long his patients began to die, both in the Hôtel-Dieu and in La Charité, in such numbers that, disappointed and broken by persecutions, he left Paris and travelled first in the provinces and then in Holland and Germany, where he was well received by those who saw him operate.

Observers of Jaques soon discovered that his operation was a great advance on the Marian, and Marechal in Paris, Raw in Holland, and Cheselden in England adopted it and put it to the test. There was one also who was deeply impressed by this procedure, and that was M. Fagon, who had shown much kindness to Jaques on his visit to Versailles, and had remained true to him even after his misfortunes in Paris. Fagon was himself afflicted with stone, and, in spite of the fact that all the best surgeons in France and Holland performed this new operation, resolved to place himself in Jaques's hands. He therefore, in the year 1700, called him to Versailles, lodged him in his own house, and persuaded him to go through a complete course of studies and dissections. This he did under the guidance of Fagon; then a series of operations were performed on dead bodies, and the parts afterwards dissected by Du Verney, the anatomist, who with Felix, the king's body surgeon, and Fagon, his future patient, discussed the various points of the operation with Jaques. As the result of these experiments he formulated his second operation, giving up the use of the round staff and using a grooved one instead. The incision

was now no longer made with the long dagger-shaped knife, but with an ordinary scalpel, the position of the incision being similar to that of his first operation. The deeper incision was, however, quite different, for, instead of passing the knife through the cellular tissue that surrounds the rectum or seeking the body of the bladder, the neck of the bladder and the prostate were cut by passing the knife along the groove in the staff, and thus incising the prostate. The rectum and pudic artery were out of danger, as the knife was not plunged blindly among the parts. Jaques now put his improved operation to the test, and cut 38 patients in Versailles without losing one. He fully recognised the help that had been given him by this staunch supporter, and he saw the value of a knowledge of the anatomy of the parts, of the advantage of the grooved staff, and of the method of making the deep incision by passing the knife along the groove. A critical time now came in Jaques's career, for not only was M. Fagon afflicted with stone but the Mareschal de Lorges was also the subject of stone. M. Fagon, who had been so largely instrumental in perfecting the operation, had actually been sounded by Jaques, when he was prevailed upon by his friends to place himself in the hands of Marechal, who had learnt to perform Jaques's operation. This he did, and was cut by him with complete success. The Mareschal de Lorges took every precaution to ensure success in his own case at the hands of Jaques. He collected 22 patients with stone who were cut by Jaques with perfect success. He then submitted to the operation himself, and died in tortures the next day. This was a fatal blow to the reputation of Jaques, and he left Paris, never to return. He travelled over the continent of Europe, and operated with great success. At The Hague the magistrates had his portrait engraved and presented him with a set of golden sounds. In Amsterdam, by the permission of the magistrates, he cut patients in the hospitals. In 1707 he was again at Versailles and visited his old friend M. Fagon. He went to Vienna, Venice, Padua, and Rome, and finally died at his native village in 1715.

# THE SPHYGMOMANOMETER AND THE SPHYGMOGRAPH

## IN RELATION TO THE MEASUREMENT OF ARTERIAL BLOOD PRESSURES.[1]

BY C. O. HAWTHORNE, M.D. GLASG.,
HONORARY PRESIDENT OF THE GLASGOW SOUTHERN MEDICAL SOCIETY (1909–10).

IT is due, I cordially recognise, to your goodwill that I enjoy the present opportunity of speaking to you on the relative values and meanings of two comparatively modern methods of observing and recording certain features of the arterial pulse; and although in doing so I shall have, I fear, to recite to you a number of propositions with which you are already abundantly familiar, I hope to be able to convince you that at least some of these propositions demand interpretations of a somewhat different order from those which are commonly placed to their credit.

The arterial pulse has, of course, always been an object of nterest and of importance to practitioners of the art of medicine, and the several varieties of its rate, of its rhythm, and of the characters of the individual beats were recognised and expounded at a very early date in medical history. I am not sure whether anyone at the present day is prepared confidently to identify each one of the 27 forms of pulse described by Galen, but I am quite sure that no modern physician proposes to enlarge that classification; and a good deal might be said for the contention that in practical clinical work the several characters of the pulse mean to-day very much what they meant to the physicians who first described them many centuries ago. But the modern spirit, inspired by science, with its universal passion for measurement, has touched the pulse as it has touched many other commonplace objects and movements. Hence has arisen the desire, in the study and examination of the pulse, to substitute for the immediate sense-perceptions and personal judgments of the physician methods carrying a capacity for numerical values and graphic record—methods, that is to say, which may be relied on to yield results unaffected by the personal bias or other defects of the individual observer. The ambition, in short, of instrumental methods in the study of the pulse is to describe the pulse in terms of exact measurement and to display its characters in graphic or pictorial record.

It may, perhaps, be said that this is a subject of but limited interest, seeing that the conditions under which medical practice is for the most part conducted are not favourable to the use of instruments of precision in ordinary pulse examinations. Such a proposition might easily be contested, but, allowing it to pass for the moment, it still remains true that instrumental methods *are* used in the examination of the pulse, and that records so obtained, and important clinical inferences based on them, occupy a somewhat prominent position in modern medical literature. Consequently, whether we like it or not, we are, individually, face to face with the necessity of endeavouring to form an opinion of the value these records possess and of the meanings they severally convey.

Now it will be allowed that one quality of the arterial pulse, which in modern medicine is being specially subjected to instrumental investigation and record, is the quality known as blood pressure. And manifestly, before we can examine or criticise these investigations and records, we must be familiar with the facts which they portray, and we must accept and understand the term "blood pressure" in one and the same sense. We must, in short, obey the elementary mandate which directs us to precede discussion by a definition of the terms to be employed.

Fortunately there is one part of the circulation—namely, that conducted in the capillaries—where there is no room for difference of opinion or of statement in the definition of the term "blood pressure." Through the capillaries, as we know, the blood flows in a steady and even current and at a constant and uniform pressure—at a pressure sufficient to move the blood along the vessels, sufficient to keep the capillaries distended, sufficient to cause certain elements of the blood to pass through the capillary walls, but, happily, at a pressure less than sufficient to produce capillary rupture. And this intracapillary blood pressure is the essential blood pressure of the body, as upon it the maintenance of the nutritive and metabolic activities of the tissues directly depends; and all other blood pressures, whatever they be, exist with this one aim and object—namely, to provide and continue a constant, uniform, and gentle blood pressure in the capillaries.

But to institute and maintain a flow of fluid or circulation in a system of closed tubes it is necessary to secure at some point in the system a rhythmical disturbance of pressures. And this, we recognise, is effected in the human body by the action of the heart, each systole of which causes a rise of pressure within its cavities, the resulting outflow of blood being guided in the desired direction by means of the cardiac valves; whilst at the following diastole there is a fall of the intracardiac pressure, and a consequent flow of blood into the cardiac chambers. Thus intracardiac blood pressure is not, as is intracapillary blood pressure, a constant and uniform level, but is, on the contrary, a repeated and rapid movement between wide extremes. Hence arises a necessity for the provision in the circulatory apparatus of some mechanism by which the wide variations of blood pressure due to the alternate systole and diastole of the heart shall be converted into the uniform and gentle pressure necessary to, and characteristic of, the capillary circulation.

It is to meet this demand that the arteries or tubes which intervene between the heart and the capillaries are provided with highly elastic walls. Into these elastic vessels at each systole of the left ventricle there is driven forcibly a parcel of blood, and while part of the force is occupied in moving the blood along the vessels, part is spent in distending or stretching the arterial walls. At the cessation of the ventricular systole these elastic walls recoil and thus cause a further displacement of blood towards and through the capillaries. There is, therefore, in the capillaries pressure and blood flow during cardiac systole, and pressure and blood flow in the intervals between successive cardiac systoles, this latter result being due to the elastic recoil of the arteries. In this way there is secured that uniform and constant intracapillary blood pressure which the physical and biological conditions of the capillary circulation

[1] An address delivered to the Glasgow Southern Medical Society.

demand; while, at the same time, the anatomical and physiological distance of the capillaries from the heart, the resistance offered to the circulation by the arterial walls, and the elastic and therefore force-absorbing quality of these walls combine to reduce the violent pressures caused by the cardiac contractions to a level compatible with capillary integrity.

But observe the unfortunate position of the arteries in this scheme of things, for their lot is, indeed, a hard one. With each cardiac systole a blow and a strain is inflicted on the arterial wall. Recovering from this, the artery recoils or moves towards a position of rest, but such a position it never reaches, for before it does so it is made to stagger under the impact of a second blow. Thus always the arterial wall is in a state of strain or tension—the tension rises with the cardiac systole and falls with the cardiac diastole, but it never wholly disappears; which is only another way of saying that always within the arteries there is a positive blood pressure—the pressure rises with the cardiac systole and falls with the cardiac diastole, but it never wholly disappears. And the arteries suffer this strain, and these repeated bangings and buffetings, not for their own pleasure and enjoyment, but in order that the capillary circulation may be conducted in calm and quietude and peace—in order that the tissues, so far at least as the capillary circulation is concerned, may dwell at ease in a land "in which it seemeth always afternoon." Or, to change the figure, it is the fate of the arteries to "wither" in order that the capillaries may be "more and more."

In any discussion on the subject of blood pressure it is only seemly and just that at least a passing word of recognition should be offered to the position, the function, and the fate of the arteries. Inelegant, unæsthetic structures, mere pipes or conduits for the transmission of fluid, the arteries may readily, at least by a superficial observer, be numbered among what the Apostle Paul calls "our uncomely parts," but when one recognises how persistently they suffer "the slings and arrows of outrageous fortune," and how uncomplainingly they discharge their altruistic functions, we may surely go further and join with the Apostle in his conclusion:

> And those members of the body which we think to be less honourable, upon these we bestow more abundant honour; and our uncomely parts have more abundant comeliness.

This, however, is but a passing allusion to what may be called the poetical or philosophical relations of blood pressure, and with these aspects of the subject, I recognise, we have at the moment no direct concern.

To revert, therefore, to a more practical note, it appears that while in the capillaries blood pressure is a uniform and constant measure, and in the heart a series of rapidly repeated excursions between a very high level and a very low, indeed a minus, quantity, blood pressure in the arteries is a continuous force, though the amount or degree of this force rises and falls with the cardiac systole and diastole respectively, and the height of the maximum and the extent of the oscillation are greater as the artery is nearer the heart, upon the action of which both maximum of pressure and extent of oscillation directly depend.

By this brief sketch, then, we may be reminded that the pressure of blood in different parts of the circulatory mechanism not only varies in degree but also in quality or kind—there is an intracardiac blood pressure, an arterial blood pressure, a capillary blood pressure, and a venous blood pressure; and each of these has both its own measure and its own character. Rather, therefore, than blood pressure there are blood pressures; and hence, when a particular figure is presented to us as a measure or index of blood pressure, it is of the greatest importance in the interests of clear thinking that we shall have a lively appreciation, both of the point or level of the circulatory mechanism at which such measurement has been taken, and also of the exact period of the circulatory rhythm in which it has been calculated.

How, now, do these considerations apply to the use of the apparatus, the sphygmomanometer, which is being largely employed at the present day to estimate what is called, usually without phrase and without qualification, *the* blood pressure? In the most common type of sphygmomanometer a broad leather armlet is strapped firmly round the upper arm; lining this armlet is an elastic bag which communicates through an indiarubber tube with the well of a mercurial manometer, so that at any given moment the pressure at all points of the system is identical and the degree of the pressure is indicated by the height to which the mercury rises on the manometer scale. After the armlet has been fixed in position the pressure in the manometer system is gradually increased by pumping in air by means of a valved ball or pump, and the increase is pushed until the radial pulse just disappears; and at this point the level of the mercury is read and is declared to be the blood pressure, the assumption being that when the pressure in the sphygmomanometer is sufficient to neutralise or overcome the pulsations in the brachial artery (as shown by the cessation of the pulse at the wrist) the pressure on the external surface of the artery must be equal to the pressure on its internal surface, and as this external pressure is indicated by the level of the mercury the figure which this reaches is announced as the index or measure of the blood pressure. Perhaps it is allowed, more or less generally, that considered as an absolute record this figure is qualified to an uncertain extent by the resistance of the soft tissues of the upper arm and also by the resistance offered by the arterial wall. But with this aspect of the question we are not now concerned. In other words, I propose to accept in the meantime, and without any discussion of the disturbing elements just mentioned, the figure recorded by the sphygmomanometer and usually announced as the measure of the blood pressure; and upon this announcement I have one or two comments to make.

First, it is evident that the figure obtained from the sphygmomanometer is not the measure of anything which can be called the general, mean, or average blood pressure, but is, on the contrary, merely the measure of a particular or individual pressure obtained from the brachial artery during a certain phase of the circulatory movement. Secondly, it is also evident that the figure recorded by the sphygmomanometer is not the measure of anything which can be called the mean or average pressure of the arterial cycle, for the record is taken only at a single point in this cycle. And as the point selected is the one at which the distending force within the artery is just overcome, it is manifest that the sphygmomanometric figure is the measure of this distending force. But the distending force within the brachial artery is most certainly the pressure of the blood as this is due to the systole of the left ventricle. Therefore the figure yielded by the sphygmomanometer is a measure of the force of the left ventricle as this reaches and influences the brachial artery; or, in more detail, it is a measure of the vigour with which the left ventricle, through the column of the blood and for an undefined period of time, acts as a distending or expanding force within the brachial artery.

It is of some importance carefully to note this definition, as the pressure of blood within the brachial (or any other) artery is, if the complete arterial cycle is contemplated, caused, or at least controlled, by two different factors; and while one of these is the systole of the left ventricle, the other is the degree of resistance offered to the circulation, as this resistance is determined by a contracted or relaxed condition of the vessels on the remote or peripheral side of the artery. But, as in the application of the sphygmomanometer, and at the moment the record is taken, the peripheral circulation in the upper limb is, by the strangling action of the sphygmomanometer armlet, for the time being practically put out of existence, it is obvious that the sphygmomanometer cannot measure the contribution which this factor—that is, the peripheral resistance—makes to the level or other character of the blood pressure. There, therefore, remains for measurement only the contribution made by the left ventricle, and hence we arrive again at the conclusion that the figure announced by the sphygmomanometer is, and only is, a measurement of the height to which, for an undefined period of time, the blood pressure rises under the stroke or systole of the left ventricle.

I have here a record which I submit as a demonstration of the accuracy of this conclusion. The patient from whom this tracing (Fig. 1) is taken has, in the language of the sphygmomanometer, a blood pressure of 175; this, in other words, is the figure at which the mercury stands when the pressure in the sphygmomanometer is just sufficient to neutralise the arterial pulsation in the upper limb. When a pulse tracing (Fig. 1) is taken it is seen that the pulse has the characteristic features of the pulsus alternans, a strong and relatively weak beat following one another alternately.

If the sphygmomanometer and the sphygmograph are applied at the same time, and the pressure in the former is raised so that the mercury touches the level 175 on the scale, the excursion of the sphygmographic needle ceases. But if the pressure is lowered, say, to 160, certain beats of the pulse come through, and it is obvious that these are the alternate stronger beats; the same thing is seen when the pressure is further lowered, say, to 150, and it is not until it is depressed to 140 that faint indications of the alternate weaker beats of the heart reach the radial artery and appear as feeble waves in the pulse tracing.

According, therefore, to the doctrine of the sphygmomanometer, this patient at one moment has a blood pressure of 175 and at the immediately following moment a blood pressure of about 145. But the conditions attending the two observations remain unchanged with one exception, and that exception is the degree of force of the cardiac systole. It is therefore a difference in the vigour of the alternating systoles which explains the difference in the two sphygmomanometric readings, and thus the facts displayed in Fig. 1 may be quoted in support of the conclusion that what the sphygmomanometer measures is the force of the cardiac systole as this arrives at the brachial artery. Such, then, and subject to the qualifications to which I have already alluded, is the contribution offered by the sphygmomanometer to the measure or estimate of the pressure of blood within the arterial channels.

We have now to consider what information relative to blood pressure is professed or offered by the sphygmograph. With the use of this instrument as an apparatus for recording the rate of the pulse, the rhythm of the pulse, and the presence or absence of pulse irregularities we are not now concerned. Our business is solely with the characters of the individual sphygmographic wave in so far as these offer, or profess to offer, information as to the height or level of blood pressure. It may perhaps be said that no one uses, or thinks of using, the sphygmograph for the purpose of measuring blood pressure. But, with great respect, I submit that this statement can only be accepted subject to considerable qualification. No doubt it is true that no one uses the sphygmograph with a view to make an absolute measurement of blood pressure—a measurement, that is, in exact numerical terms. But surely it is also true that we are repeatedly presented with sphygmograms which are announced as indicating high blood pressure on the one hand or low blood pressure on the other. And the terms "high" and "low" in such a context are manifestly terms of measurement—of comparative, not of absolute measurement—but, all the same, terms of measurement. Therefore it is fair to say that the sphygmograph is claimed as an instrument which possesses the ability to proclaim, at least in comparative terms, the height or level of blood pressure; and, indeed, diagrams such as those seen in Fig. 2 are, with their corresponding legends, familiar objects in every textbook.

What, then, are the features of the sphygmographic wave which present themselves as guides in the endeavour to estimate the degree of blood pressure? These characters are found, I venture to remind you, mainly on the descending line of the wave. When this line is sloping or oblique, with a second or tidal wave, at, or nearly at, the same horizontal level as the primary or percussion wave, and with a third or dicrotic wave relatively inconspicuous and high up on the descending stroke, the message of the sphygmograph is read as a message of "high" blood pressure (Fig. 2, A); while, on the contrary, when the wave falls suddenly and promptly, with a tidal wave either absent (Fig. 2, C), or, if present, well below the horizontal level of the primary wave (Fig. 2, B) and a dicrotic wave well marked and low down on the descending line, the sphygmographic reading is recorded as one of "low" blood pressure. These are the facts upon which, we are taught, we may rely in an endeavour, by means of the sphygmograph, to determine whether the blood pressure or arterial tension is "high" on the one hand or "low" on the other.

Such, then, are the current doctrines of the sphygmomanometer and the sphygmograph relative to the measurement of blood pressure, and it is manifest, if these doctrines are valid, that the two instruments in any given instance will deliver an identical message—they will speak in equal tones and will prophesy with a unanimous voice. Or, in practical phrase, when in any patient the sphygmomanometer announces a high record (say 130 or upwards) the sphygmograph will produce a picture of the type seen in Fig. 2, A, while when the sphygmomanometer intimates a low blood pressure (say 100 or less) the sphygmographic tracing will follow the pattern of Fig. 2, B or C. And there are many cases in which this anticipated harmony or correspondence between the deliverances of the sphygmomanometer and those of the sphygmograph is fully and exactly realised. Thus in Fig. 3 is shown a group of pulse-tracings each one of which, in the language of the sphygmograph, is a proclamation of "high" blood pressure—the descending line of the sphygmographic wave is oblique or sloping, the tidal wave is at, or nearly at, the same horizontal level as the percussion wave, and the dicrotic wave is slight and is high up on the descending line. And with equal distinctness the sphygmomanometer, in each case, announces that the blood pressure is "high"; in the first case the record is 210, in the second 210, in the third 200, and in the fourth 165, all of these numbers being far above the normal or average sphygmomanometric level. Again, in Fig. 4 is seen a group of pulse-tracings every one of which, described in sphygmographic terms, is a distinct intimation that the blood pressure is "low"—the pulse wave falls more or less suddenly, the tidal wave is absent, and the dicrotic wave is relatively conspicuous and is low down on the descending line. And the sphygmomanometer, in each instance, again speaks to the same effect, for the figures 95, 98, 98, and 105, as marked on the tracings, are as sphygmomanometric records distinctly below the usual or average reading.

Therefore, so long as we confine our observations to such series of cases as are represented in Figs. 3 and 4, we may entertain and cherish the comfortable conviction that the sphygmomanometer and the sphygmograph in their deliverances on the subject of blood pressure confirm and support one another—that they announce similar or corresponding findings, the one in terms of exact measurement, the other in the form of pictorial facts on which a comparative estimate may be securely rested.

But I have now to ask your attention to some records which seriously disturb this apparent agreement between the sphygmomanometer and the sphygmograph, which, indeed, completely and absolutely explode and destroy it. The first evidence to this end I show in Fig. 5. Here is a group of pulse-tracings taken from different patients and presenting widely different characters. Especially do they differ among themselves in those features which are presented as pictorial guides to the estimation of the level of the blood pressure. In the earlier members of the series it is written in unmistakeable characters that the blood pressure is "high," while in the later tracings the facts, with equal distinctness, announce that the blood pressure is "low." Yet, and this is the startling fact, the sphygmomanometer proclaims that in each of these cases the blood pressure has one and the same level—namely, 175 mm. of mercury. According to the one instrument, therefore, all of these patients have one and the same blood pressure; according to the other the blood pressures in the several cases are widely different.

Clearly, then, we can no longer say that the sphygmomanometer and the sphygmograph speak in equal tones and deliver an identical message, as with one and the same announcement from the sphygmomanometer there may, we see, exist sphygmographic pictures which, as displays of the level of the blood pressure, vary in their characters and meanings between the widest possible extremes. But this is not all. Not only with a uniform sphygmomanometric reading may the pulse pictures vary as just described, but the records of the two instruments may appear in direct and mutual antagonism. And the contradiction may, as one may say, be in both directions. In a given case, for example, the sphygmomanometer may intimate a "high" blood pressure and the sphygmograph may protest that the pressure is "low"; or, on the other hand, the sphygmomanometer may indicate that the pressure is "low," while the sphygmograph writes distinctly that the pressure is "high." Here is the demonstration. Fig. 6 shows a group of pulse-tracings which in sphygmographic language announce more or less distinctly the existence of "high" blood pressure. Yet in every instance the measurement effected by the sphygmomanometer is a measurement of "low" pressure, the several numbers running 75, 80, 86, 98, 100, and every one of these being distinctly below anything which can be called the normal or average sphygmomanometric level.

FIG. 1.

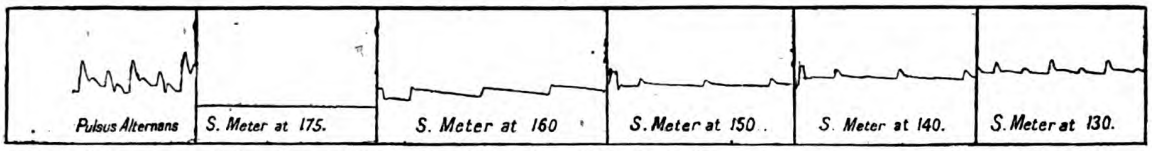

Fig. 1.—Sphygmogram (pulsus alternans) showing the effect on the radial pulse of different degrees of pressure applied to the brachial artery by the sphygmomanometer. With the pressure at 175 mm. Hg. all pulsations cease; at 160 and 150 only the alternate and stronger cardiac systoles reach the radial artery; and it is not until the pressure is reduced to 140 that the alternate weaker beats affect the tracing.

FIG. 2.

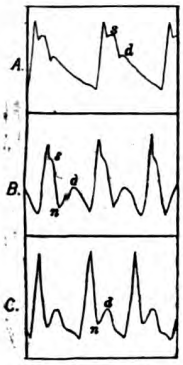

FIG. 3.

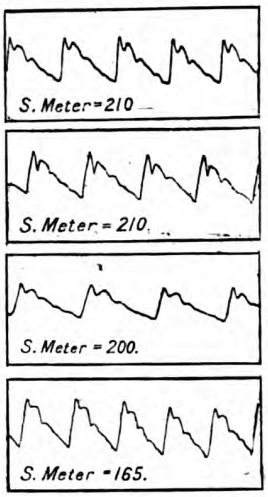

FIG. 4.

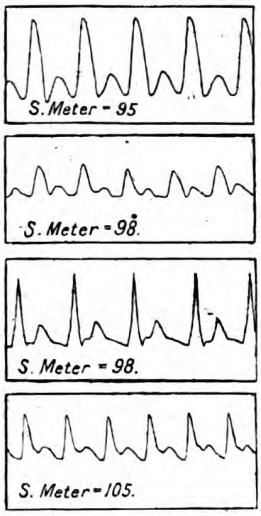

Fig. 2.—A, Pulse of high arterial pressure. B, Pulse of low arterial pressure showing slight tidal wave. C, Pulse of low arterial pressure without tidal wave. *s*, Tidal wave; *d*, dicrotic wave; *n*, pre-dicrotic or aortic notch. (Copied from Dr. Jas. MacKenzie's book on "The Pulse.")

Fig. 3.—Sphygmograms indicative of "high" arterial pressure associated in each case with a "high" sphygmomanometer record.

Fig. 4.—Sphygmograms indicative of "low" arterial pressure associated in each case with a "low" sphygmomanometer record.

FIG. 5.

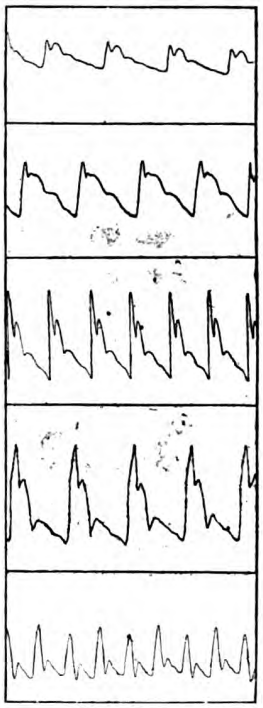

Fig. 5.—Sphygmograms of different and even of opposite character with, in all, one and the same sphygmomanometer record—viz., 175 mm. Hg.

FIG. 6.

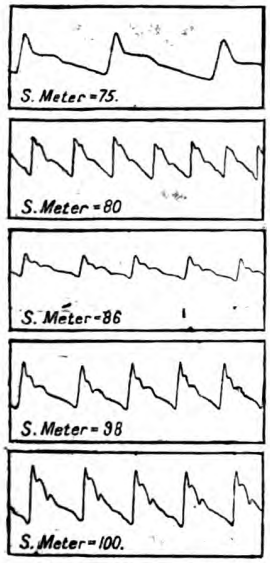

FIG. 7.

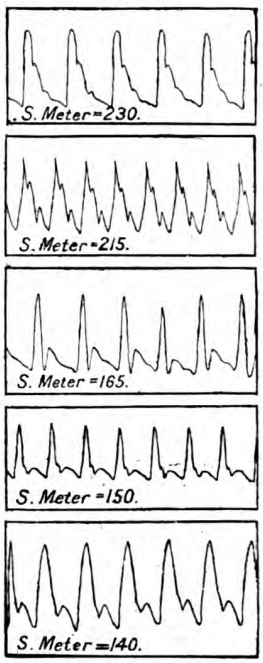

FIG. 8.

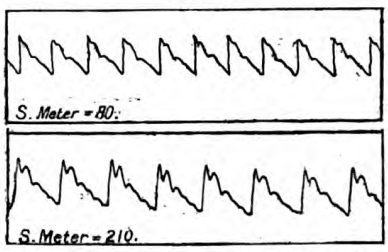

Fig. 6.—Sphygmograms indicative of "high" blood pressure associated in each case with a "low" sphygmomanometer record.

Fig. 7.—Sphygmograms indicative of "low" blood-pressure associated in each case with a "high" sphygmomanometer record.

Fig. 8.—Sphygmograms of similar or identical patter with very different (80 in the one case, 210 in the other) sphygmomanometer records.

Again, in Fig. 7 is another group of pulse-tracings, each one of which translated into sphygmographic terms carries a measure of "low" blood pressure. But the sphygmomanometer tells an entirely different story. It says, indeed, that in each of these patients the blood pressure is above, and in most of them far above, the normal, the actual numbers ranging from 230 to 140, while an average sphygmomanometric reading is somewhere about 120. In both of these groups, therefore, the sphygmomanometer and the sphygmograph plainly do not speak with corresponding, but with contradictory, voices, and the anticipated harmony has failed to arrive. Hence, to present the position in a sentence, we find that while in certain instances the sphygmomanometer and the sphygmograph are in apparent agreement, there are other instances in which they do not agree, and in which, indeed, the messages delivered by the two instruments relative to the level or height of the blood pressure are directly and mutually contradictory.

In these circumstances what is the unfortunate clinical instrumentalist to do? Possibly, as he contemplates the sphygmomanometer and sphygmograph in the light of the records here exhibited his feelings may be disposed to express themselves in the well-known lines:—

> "How happy could I be with either,
> Were t'other dear charmer away,"

and he may perhaps be impelled to the conclusion—

> "But as you both tease me together,
> To neither a word will I say."

If, however, he must, or thinks he must, make a choice—selecting one method and ignoring, as is the current fashion, the teaching of the other—shall he choose the sphygmomanometer with its attractive air of precision and accuracy, or shall he prefer the less precise but more picturesque displays of the sphygmograph; or, again, rather than either, shall he determine to fix his faith on his own trusty three fingers on the radial artery and brush aside both sphygmomanometer and sphygmograph as equally useless and equally untrustworthy?

Well, the suggestion I beg to offer in this dilemma is that our clinician shall not take any one of the three courses thus proposed to him, but that, on the contrary, while striving always for the "educated finger" he shall use *both* the sphygmomanometer and the sphygmograph, but in doing so he shall apply to their records canons of interpretation somewhat different from those which are generally current. For each of these instruments certainly gives us some information on the subject of blood pressure. The sphygmomanometer, if it does nothing else, at least tells us what amount of pressure is necessary to overcome the pulsations of the brachial artery; and no one questions that the ascent of the sphygmographic wave coincides with, and is due to, a rise of intra-arterial blood pressure, and similarly, that a descent of the wave represents, and is dependent on, a fall of such pressure. But as, *when tested by the claims usually made on their behalf*, these two instruments, though sometimes in apparent agreement, are often found in a state of open, conspicuous, and flagrant contradiction, surely the reasonable and common-sense conclusion is that it is the "claims" and not the instrument which are at fault. And the solution of the mystery is to be found, I suggest, in a recognition of the fact that blood pressure, as any other pressure, has other qualities than mere level or height, and that one of these is continuance or duration.

The measurement of the height to which blood pressure rises is one question, the measure of the endurance of the pressure *in time* is another and an entirely different question. Relatively high or relatively low and independent of the fact of high or low, blood pressure may manifestly be either prolonged and abiding, or brief and evanescent; whatever be the maximum attained, the decline therefrom may be either slow and gradual, or sudden and abrupt. Now upon this second question—namely, the duration of the maximum pressure and the manner of pressure decline, the sphygmomanometer does not, and cannot, give us any information. It may announce the measure of the force of the ventricular systole as this reaches the brachial artery, but it certainly cannot announce the time during which the blood pressure so caused continues, for, given a certain maximum of pressure within the brachial artery, the sphygmomanometric pressure necessary to neutralise or overcome this will be one and the same whether such maximum persists for a relatively prolonged period or whether, on the contrary, its duration is but for a moment.

On the other hand, the sphygmograph, whatever be its other values, certainly does not contribute any reliable information as to the maximum level to which the blood pressure rises, for, as we have seen, with one and the same maximum record in different patients the pulse pictures may be of directly opposing types (Fig. 5), and with different maximum records the pulse pictures may be of one and the same type (Fig. 8). But as, without doubt, the descending line of the sphygmographic wave corresponds more or less closely to the movement of pressure decline within the artery, we must surely find on contemplation of this line some information as to the manner of such decline. In other words, if the maximum pressure, whatever it be, is relatively prolonged, and the decline therefrom is slow and gradual, the sphygmogram will announce these facts in a sustained wave followed by a sloping or oblique downstroke (Fig. 2, A); while, on the contrary, when the maximum pressure, whatever be its absolute reading, is promptly followed by a sudden fall, the sphygmographic wave will present a sharp apex and a sudden and abrupt descent (Fig. 2, B C).

If we admit these conclusions, and if, further, we recognise that as the sphygmographic picture conveys no information as to the height or level of the blood pressure, the terms "high" blood pressure and "low" blood pressure applied to sphygmograms are misleading and inexact, and if, once again, we agree to replace these terms by the phrases "well-sustained blood pressure" and "ill-sustained blood pressure" respectively, all the apparent contradictions and mutual confusions of the sphygmomanometer and the sphygmograph cease and disappear.

The two instruments not only are not, but cannot possibly be, mutually contradictory, for they speak not of the same but of two different and independent things—the one of the level to which for an undefined period of time the blood pressure rises, the other of the relative duration of the pressure and of the manner of its decline. Each has its own value, each has its own function, and the information obtained from the one supplements that conveyed by the other; but the activities of these instruments are displayed, not on the same but on different planes, and therefore cannot possibly come into mutual conflict and collision.

It must be added that even when sphygmomanometer and sphygmograph have both been employed, there still exists a deficiency in our instrumental appreciation of the qualities of blood pressure, as neither of these instruments records the minimum level to which the intra-arterial pressure falls. To measure this so-called diastolic pressure many methods have been suggested, but none of them can be accepted with complete confidence, and the absence of this measurement lends emphasis to what is implied in the argument of this address—namely, that the customary announcement of the maximum sphygmomanometric figure on the one hand, or the presentation of a sphygmogram on the other, is in the individual patient anything but a complete, final, and exhaustive statement on the clinical aspects of blood pressure.

Whether I have succeeded in convincing you that the positions as I have presented them are well founded and secure I, of course, may not dare to say. But, thanks to your invitation, I have at least had the opportunity of stating these positions, and I now, with great respect, leave the verdict upon them to the decision of your better judgment.

Harley-street, W.

---

GERMAN UROLOGICAL SOCIETY.—The Deutsche Gesellschaft für Urologie announces that the third congress of the society will take place in Vienna from Sept. 11th to 13th. The chief subjects for consideration will be: (1) The Permanent Results of Nephrectomy for Tuberculosis, reported by Dr. Israel of Berlin and Dr. Wildbolz of Zürich; and (2) the Clinical Importance of Urethroscopical Methods, reported by Dr. Oberlaender of Dresden and Dr. Wossidlo of Berlin. Applications to take part in the discussions on these subjects by means of papers and demonstrations must be made before June 1st to the office of the society, Maria Theresienstrasse, 3, Wien, IX. Dr. O. Zuckerkandl is the president and Dr. Kapsammer is the secretary of the society.

# EYE-STRAIN IN RELATION TO THE GENERAL HEALTH.

BY JAMES HINSHELWOOD, M.A., M.D. GLASG.,
SURGEON TO GLASGOW EYE INFIRMARY, AND LECTURER ON OPHTHALMOLOGY IN THE GLASGOW WESTERN MEDICAL SCHOOL.

EVERYTHING appertaining to the well-being of the patients under his care is of importance to the general practitioner. With regard to eye symptoms, however, he is too apt to regard these as of importance only to the specialist and therefore outside of his sphere of interest. I wish, therefore, to direct attention to the close relationship which frequently exists between eye-strain and the general health, how these influence one another, and how therefore the practitioner must be familiar with the far-reaching effects of eye-strain if he would deal successfully with these sufferers, who will generally apply to him in the first place for the relief of their distressing symptoms.

Eye-strain frequently acts by exhausting the nervous system of the patient, and hence through the medium of brain and spinal cord often has a profound and far-reaching effect on the functions of the various organs of the body and on the general nutrition of the patient.

I am not one of those who would attribute "all the ills that flesh is heir to" directly to the varied effects of eye-strain. There has been a tendency on the part of some writers, especially in America, to exaggerate the far-reaching effects of eye-strain, and this has given rise to a certain amount of discredit and scepticism regarding the subject. But as experience becomes wider one becomes more and more impressed with the fact that eye-strain has often a most prejudicial effect on the general health of the patient, and that great improvement in this may often be brought about simply by the relief of the eye-strain.

An important thing to bear in mind is that whilst eye-strain often manifests itself by pain or discomfort in the eye itself, this is not always the case. In many cases the eye-strain is accompanied by no pain or discomfort in the eye, but by symptoms altogether outside of the eye itself, and these are the cases which often escape the notice of the practitioner unless his attention has been specially directed to the subject. It will be well for him, therefore, to thoroughly familiarise himself with these symptoms of eye-strain, which arise apart from the eye itself, and this knowledge will often be of the greatest service in ministering to the well-being of the patients under his charge.

Another most important thing for the practitioner to bear in mind is that the symptoms which I am about to describe as arising from eye-strain may be due to a very small error of refraction, and hence may never be suspected either by the physician or by the patient. I think this is peculiarly true of astigmatism, where a very small error, even 0·25 D., may give rise to distressing symptoms. In fact, my experience is that the small amounts of astigmatism give rise to symptoms of discomfort more frequently than the high degrees. The explanation, I think, is that a person with a high degree of astigmatism makes no effort to see better, as his vision is so defective, but that the smaller degrees of astigmatism, only causing a slight blurring, induce the patient to make a continuous accommodative effort to counteract it and get clear images, and hence cause continuous ciliary strain. These patients with slight degrees of astigmatism have good vision, and many of them pride themselves on their good vision, and are rather indignant at the idea of their symptoms being due to eye-strain. Patients with hypermetropia and suffering severely from eye-strain may have absolutely normal vision if tested by the test types, and it is this fact which completely misleads frequently both the patient and physician as to the true cause of their symptoms.

Another reason why eye-strain, as a cause of symptoms, is often overlooked is because the patient is already wearing glasses and has derived little or no benefit from them. It cannot be too strongly emphasised that to derive benefit the refractive error must be exactly and properly corrected. In most cases this cannot be satisfactorily accomplished without examination of the patient under homatropine or atropine. This can be properly done only by an ophthalmic surgeon, and nothing requires greater care than the fitting of patients with appropriate glasses. In many cases, as when there is marked inequality of refraction in the two eyes, the problem is a very difficult one and requires great care, thought, and experience.

Of all the reflex symptoms of eye-strain, the most frequent is headache, and yet very many cases of ocular headache go on suffering for years without the true cause being suspected. It is important to bear in mind the points with relation to eye-strain which I have already mentioned—viz., that eye-strain may be present without the patient experiencing any discomfort or pain in the eyes; that eye-strain may be present although the patient possesses good and even normal vision as tested by the types; and that glasses will not give relief unless the refractive error has been adequately and exactly corrected. Bearing in mind these facts, it is evident that the only safe rule of practice is that every patient suffering from headache of a recurring or chronic character should have his refraction carefully examined by someone thoroughly competent to make such an examination.

The ocular headache may occupy any position—frontal, vertical, or occipital, and I have frequently seen pain even at the back of the neck due to eye-strain. Whilst the situation of the headache does not guide us to the diagnosis, in the majority of cases it is frontal or vertical. Ocular headache is generally absent in the morning. If the patient has had a good night's sleep he wakens up free from headache. It begins in the course of the day and gradually increases in intensity as the day goes on. This is always the case with a pure ocular headache. This is in contrast to the character of the toxic headache, which is worst in the morning after a good night's sleep, and becomes better when the patient gets up and exerts himself. The toxic elements accumulate in the blood during sleep and exercise helps in their elimination. In many cases of headache we have a combination of the toxic and ocular, and in such cases the patient wakens with a headache, which, however, gets worse as the day goes on. In such cases the cure of the patient can only be accomplished by the relief of the eye-strain and the removal of the toxæmia, of which constipation is a frequent cause. Anæmia and eye-strain are also a frequent combination in the production of headache, and cure can only be brought about by the removal of eye-strain and the internal administration of drugs for the cure of the anæmia.

This complex origin of headaches is a point that is very frequently lost sight of, attention being given to one factor only in the case. It is to be remembered that whilst eye-strain is frequently the sole cause of headache, there are other cases where the eye-strain is only one factor in its production. The relief of the eye-strain will benefit the patient, but complete relief will not be given until all the causal factors have been dealt with and removed.

It is very remarkable how much the general health of the patient benefits by the removal of a chronic headache. Even if the headache has not been very intense, its frequent and often daily presence produces in the patient great mental depression, which through the influence of the nervous system has a powerful influence on the nutrition of the body as a whole. The complete removal of this headache, which has made the patient's life miserable, lifts him into a new world, and the general condition of the patient, both mental and physical, is enormously benefited thereby.

In addition to definite headache patients often complain of peculiar sensations in the head, which disappear on the relief of eye-strain and which are undoubtedly due to it. A feeling of pressure or tension in the head is the most common of the head sensations apart from pain. Less frequently I have heard patients complain of a feeling of tingling or crawling over certain areas of the head, and in some cases the patients could not venture to describe the sensation further than remarking that there was a very peculiar feeling in the head, always produced by the use of the eyes.

I have seen several cases of distressing insomnia which were directly due to eye-strain and which disappeared completely when the eye-strain was removed. The most striking case of this kind I saw about a year ago. The patient suffered so much that he became neurasthenic with lowering of the general nutrition of the body, and had been away from his work entirely for about

four months during the preceding winter. He was a hypermetrope with astigmatism and was engaged at an occupation where there was great and continuous eye-strain. At night after his day's work he was so exhausted that he was unable to do anything, and when he went to bed he could not sleep. This state of affairs gradually impaired his general nutrition and especially exhausted his nervous system, so that he felt himself unable for his work and was away from it for four months. There being both hypermetropia and astigmatism, there was a constant strain on his accommodation, so that this patient suffered severely. I prescribed two pairs of glasses for him, one for constant wear and the other for near work, which put his accommodation in a state of rest. It was very remarkable to see the speedy improvement in this patient's condition. He had no longer the sense of exhaustion after his day's work and got a good night's sleep after going to bed. This brought about a very rapid improvement in the patient's general well-being and condition. Since wearing his glasses he has been able to go on steadily with his work without any difficulty.

I have seen several cases where the patients had been using hypnotics for considerable periods, but when their refractive error was properly corrected and eye-strain completely relieved they were able to dispense entirely with their hypnotics in a very short period of time. In all patients using the eyes much for near work and suffering from insomnia eye-strain should always be thought of as a possible cause.

The condition of nervous exhaustion commonly known amongst brain workers as "brain-fag" is very frequently simply due to eye-strain. Those engaged in pursuits which necessitate the close and continuous use of the eyes for reading and writing often experience a sense of prostration and exhaustion, frequently described as brain-fag, nerve exhaustion, and neurasthenia. The period during which the individual can work may become gradually more limited until he is wholly incapacitated from further effort by this increasing sense of exhaustion and prostration. In such cases I would strongly urge the very careful examination of the refraction of the eye. In such patients reading and writing constantly from eight to twelve hours a day, a very slight refractive error often produces a peculiar sense of exhaustion which is mistaken for cerebral exhaustion. I speak from experience of the great benefit derived in many such cases by the correction of refractive errors, often very slight. The relief of the eye-strain soon led to the disappearance of the sense of exhaustion at the end of the day's work and what had been for years regarded as "brain-fag" was seen to have been in reality "eye-fag."

Choreiform movements of the facial muscles in children are frequently due to eye-strain and disappear when the eye-strain is relieved by the prescription of a suitable glass. The spasmodic movements are most frequently met with in, and sometimes confined to, the orbicularis palpebrarum muscles, so that the patient is constantly blinking, and is often thought to be suffering from a mild attack of chorea. A large proportion of such cases are due to eye-strain, and when this is so the spasmodic movements will be greatly relieved or even abolished temporarily by the use of atropine, but permanent relief is only obtained by the wearing of suitable glasses. Although the spasmodic movements are often confined to the orbicularis muscles, they may extend to the facial muscles, and these cases are even more likely to be mistaken for cases of chorea.

Vertigo is another symptom sometimes produced by eye-strain. Most are familiar with vertigo as a symptom of cerebral disease, of aural disease, of gastric disturbance, and of several diseases of the nervous system. We are all familiar also with ocular vertigo, due to paralysis or paresis of an ocular muscle, and which always disappears on the closure of one eye. Few, however, think of the possibility of vertigo as the result of eye-strain. I have seen two cases where this was so severe that the patients were supposed to be suffering from disease of the nervous system. In all the cases of vertigo I have seen due to eye-strain it has been associated with hypermetropia or hypermetropic astigmatism, and rapidly disappeared after relief of the eye-strain by the prescription of appropriate glasses. In all cases of vertigo, therefore, which cannot be traced to a definite cause, and which do not yield to treatment, eye-strain ought to be thought of as a possible cause, and the patient's refraction carefully examined and any defect corrected. Eye-strain sometimes plays an important part as a causal factor in dyspepsia, and many cases of dyspepsia, though relieved by drugs and dieting, will not be cured until the factor of eye-strain is completely eliminated by the prescription of suitable glasses for the patient. The nervous system plays a most important part in the causation of many forms of dyspepsia, and it is frequently through the exhaustion of the nervous system by prolonged eye-strain that the functions of the stomach are deranged. It is in the acid form of dyspepsia especially that I have found eye-strain play an important part. In this form of dyspepsia the discomfort comes on a considerable time after food and is relieved by food. This form of dyspepsia is nearly always associated with a lowered tone of the nervous system. It is an exceedingly obstinate form of dyspepsia to treat, as drugs seem to have little effect on it apart from the temporary relief of symptoms. Cure is to be brought about only by an improved tone of the nervous system, and in some cases the relief of the nervous exhaustion produced by eye-strain is the only possible way of effecting this and so curing the patient.

I have said nothing of the local manifestations of eye-strain in the eye or its appendages. These are well known, and their very presence at once directs the attention both of patient and physician to eye-strain as their probable cause. I have in these observations limited myself to discussing the symptoms of eye-strain outside the local manifestations, with which I have become familiar in my daily work as an ophthalmic surgeon. My purpose has been to call attention to conditions often profoundly affecting the general health of the patients which are not sufficiently known to the practitioner as possible results of eye-strain, and yet where the removal of this factor is in many cases the only possible means of giving the patients relief.

Glasgow.

## DIFFUSE LATENT LABYRINTHITIS: ITS DANGERS IN THE RADICAL MASTOID OPERATION.

BY JAMES HARPER, M.A., M.B., CH.B. GLASG.,
FORMERLY HOUSE SURGEON TO THE HOSPITAL FOR DISEASES OF THE THROAT, GOLDEN-SQUARE, LONDON.

AMONG major surgical operations that known as the radical mastoid operation is considered to be one of those which may be performed with practically no danger to the life of the patients. Large numbers of this operation are performed yearly with such gratifying results that operators are inclined to be lulled into a false sense of security and to point to what are unfortunately in some cases only apparent successes as proof of the almost non-existence of danger.

All surgeons of experience, whether their work brings them into contact with aural work or not, recognise the grave danger there lies in aural suppuration as regards intracranial complications. They know the intimate connexion there is between these two conditions, and when in the course of aural suppuration symptoms arise which point to a suspicion of intracranial mischief they do not hesitate in advising more radical treatment for the ear than that which it has been receiving.

Another type of case for which advice is continually being sought is that of a patient who for a number of years has had a discharging ear. All the recognised methods of conservative treatment suitable to the case have been tried without success, and the patient now seeks advice as to whether something cannot be done to rid him once and for all of this troublesome affliction. If the hearing be good the surgeon may counsel waiting a little longer, but if, as is the general rule, the hearing has gone or has practically disappeared, the treatment generally advised is the radical mastoid operation. Having tendered this advice the surgeon is asked the usual questions: Is there any danger and will this operation stop the discharge?

The answer to the first question is that with the exception of the risk necessarily attached to an anæsthetic the danger to life is practically non-existent. The answer to the second question is in the affirmative. These are the two replies usually given. Yet most of us who have had experience of aural work, or who have been following the literature of the

subject, can call to our minds cases which did not fulfil these expectations; how an apparently uncomplicated case on which the radical mastoid had been performed was carried off in the course of a few days by a most virulent form of meningitis. The operation had been performed with the usual care and the labyrinth had been in no way injured, yet on post-mortem examination the labyrinth is found to be destroyed. Cases of exactly this type appear again and again, and we ask ourselves the questions, Could these results be foreseen, and being foreseen could they be avoided?

In considering the second question I wish to exclude those cases in which there is a tuberculous or syphilitic affection or in which there has been some flaw in the after-treatment of the operation. Immediately after the operation the patient as a rule makes a good recovery and progress is satisfactory. But as time goes on the ear shows a great reluctance to heal. There is always a little discharge which varies in quantity from day to day, but never absolutely dries up. This goes on for a month or two, and in some cases for several years, till the patient is again under treatment—this time for cerebellar abscess. We again ask ourselves the questions, Could we have foreseen this result even in those cases which occurred years after the original operation? and having foreseen could we have avoided the non-healing and the intracranial complication?

Results such as these recorded for a long time puzzled surgeons. True, on post-mortem examination in a large number of the cases which died from meningitis the labyrinth was found to be diseased. But there had been a total absence of symptoms which could suggest a possible labyrinthine involvement either before or after the operation. In the same way those cases which suffered from cerebellar abscess were found in the majority of instances to have a diseased and totally destroyed labyrinth. But here also there had been no symptoms which pointed to a possible affection of that organ.

The careful researches of Ruttin and Bárány have given us the key to these conditions, and they have shown us how in the majority of cases such untoward results may be avoided. Various observers have recorded the results of their investigations on the labyrinth in health and disease, but it has been left to Bárány, who used them as a basis of his own researches, to give us a sure method of testing the labyrinth and thus come to a certain opinion as to its condition. In a former article I drew attention to these tests, but a short *résumé* may be not out of place here.[1]

There are three tests on the labyrinth—the rotatory, the galvanic, and the caloric. Of these only the rotatory and the caloric are of practical value. They both have for their object stimulation of the labyrinth by causing a flow in the endolymph of the sensitive semicircular canals. In the rotatory test the patient is turned in a revolving chair. During rotation there is a nystagmus in the direction of the turning, but on stopping there is a nystagmus in the opposite direction.

It is a well-known fact that if the ear be syringed with water above or below the temperature of the body there is caused, accompanied by other phenomena, a nystagmus of both eyes. In 1881 Babinsky, while experimenting on animals, syringed the ears of rabbits with cold water and found he got nystagmus. He continued the syringing and burst through the membrana tympani and also the oval window of the labyrinth. The water poured through the labyrinth into the brain, his animals dying from meningitis. He was wrong, however, in concluding that the nystagmus which he got before perforation of the oval window was from the brain.

Bárány has shown that if an ear with a healthy labyrinth be syringed with cold water we get a nystagmus towards the other side, while if hot water be used—i.e., water above the temperature of the body—we get a nystagmus to the same side. This is brought about by causing a cooling or a heating of the endolymph in the canal which is nearest the water, thereby setting up a flow in the fluid which is necessarily microscopic. This is called the caloric test. Various other phenomena accompany this nystagmus—giddiness, disturbance of equilibrium, and nausea, but these only usually occur if the rotation or syringing be continued too long. The nystagmus is the first and most constant symptom to appear, and it is on it that we rely for any diagnostic value. There are two conditions in which the caloric test cannot be used—namely, where masses of cholesteatoma fill up the cavity of the middle ear, or where the external meatus is so constricted as to hinder the passage of a stream of water.[2]

The practical utility of these two tests is obvious. Should the labyrinth be destroyed by trauma or disease, on their application there will be no resultant nystagmus from the diseased ear.

The labyrinth may be affected in various degrees by aural suppuration from a small circumscribed local labyrinthitis to total destruction of the labyrinth by acute suppurative labyrinthitis. The affection passes through the various stages from the simple form to the acute, but the time necessary for a circumscribed labyrinthitis to change into the acute suppurative form varies very greatly in different cases. In some patients the transition takes place in a few hours, in others it takes months or years. But while this is so, as long as the disease has not progressed to the acute suppurative form the patient is to all intents and purposes safe from intracranial complications. If, however, acute suppurative labyrinthitis has set in, the patient is in grave danger. Should the case not be operated on at this stage there are two possible endings to the picture. In most cases meningitis now sets in, usually in a very virulent form, and death closes the scene, or we have diffuse latent labyrinthitis. It is to the grave dangers of this latter affection that I would desire to draw attention.

Fortunately, in the majority of cases the onset of acute suppurative labyrinthitis is well marked. The patient is acutely ill and advice is sought. But this is not always so. Indeed, during the last eight months I have met with three cases in which the labyrinthine function was totally destroyed by middle-ear suppuration, but in which the patients could give no history of labyrinthine trouble other than attacks of giddiness of no great severity. In one case, that of a woman, 24 years of age, whose left ear had been discharging since the age of 14 years, after scarlet fever, there was no history of labyrinthine trouble at all, and it was only on the careful application of the rotatory and caloric tests that one became aware that there was more in the case than merely a discharging ear.

As has been already stated, the labyrinth may be affected in varying degrees by aural suppurations. The simplest form is that of circumscribed labyrinthitis. In this condition only a part of the labyrinth is affected, varying from a small portion of one of the canals, usually the horizontal, to the whole of the vestibule or cochlea, but never both vestibule and cochlea together. Here the affection is purely local. Only a part of the labyrinth is affected, and beyond the surrounding zone of inflammation the labyrinth is normal as regards its function. If the cochlea be not affected there will be some hearing, but always there is present the "fistula symptom." This symptom, which is pathognomonic of circumscribed labyrinthitis, is elicited as follows. By means of a pneumatic speculum the air in the external auditory meatus is compressed or rarefied. On compression we get a movement of the eyes towards the diseased side and on rarefaction to the opposite side. During this stage of the disease the patient is safe from intracranial complications and many cases go no farther. Should the radical mastoid operation be performed the fistula, as a rule, becomes covered over by newly-formed bone, and the labyrinthine function becomes normal. Some fistulæ, however, are not covered by bone, but by a thick layer of fibrous tissue, and in a number of such cases the fistula symptom remains.

The next stage in the disease is that of serous labyrinthitis. Should the case of circumscribed labyrinthitis be not operated on it will, after an interval which varies much in different cases, go on to this condition. Here the whole of the labyrinth is affected, but there remains some function. We can imagine the whole of the endolymph as congealed into a mass, jelly-like in consistence, but there is no actual suppuration throughout the labyrinth. Well-marked vestibular symptoms are present, and there is a strong nystagmus to the opposite side. Hearing, however, may be absent or present, while the caloric test may or may not elicit some response; but there is always present either a certain amount of hearing or some caloric reaction, or perhaps a little of both. In this stage the patient is also safe from

[1] THE LANCET, May 7th, 1910, p. 1266.

[2] In these cases the rotatory test may be used.

intracranial complications, but the transition to the acute suppurative type is as a rule rapid. The objective symptoms generally do not increase in severity, but any hearing or caloric reaction which was present has now disappeared. While the various degrees of labyrinthine implications may be successively observed in many cases, yet there are some in which the changes are so rapid that the first picture which is presented to the surgeon is that of acute suppurative labyrinthitis. Should operative interference be not immediately undertaken there are three possible endings, meningitis, brain abscess, or latent labyrinthitis. Should there be no immediate complication, in about a fortnight all symptoms have disappeared. The vestibular symptoms with the accompanying nystagmus will have passed away, the nystagmus being the last to disappear. The picture now presented to us is that of an apparent case of chronic middle-ear suppuration in no way different from the many hundreds we see yearly. On closer examination, however, we find the hearing is completely destroyed and on application of the caloric test there is no response. Before the introduction of this test it was impossible to diagnose this condition. Such cases were treated by the ordinary radical mastoid operation, and the surgeons were at a loss to explain the unfortunate complications set up. True, post-mortem examination showed that in the majority of such cases the labyrinth was diseased. As a rule it was found to be the seat of suppuration, and the question arose as to whether this condition was the cause of or accompanied the intracranial mischief.

Latent labyrinthitis has two definite characteristics. The hearing is totally destroyed, and there is no response to the caloric test. If we find a case of middle-ear suppuration with these two symptoms we may safely conclude that the labyrinth is destroyed, and on examination of such a labyrinth we find that the whole of the labyrinth is disintegrated. A certain number of these cases if left alone will recover. Nature herself can set up a barrier against the inward progress of the disease and the labyrinth is gradually cast off piece-meal. If such a case be left to itself, in all probability there will be no further trouble, but such a part will always be a place of least resistance. The dangers are obvious. Cases of middle-ear suppuration are very liable to recurrent attacks of what are either new infections or exacerbations of the old infection. Now each time this occurs there is a danger of the healed labyrinth again becoming the seat of disease. While some cases of latent labyrinthitis, if left to themselves, would heal up, yet this is not always so. The process gradually makes its way inwards until it reaches the cranial cavity. Nature has not been able to throw out a sufficiently strong barrier to stop its progress, and, indeed, MacEwan has shown that frequently the sclerotic ostitis is in the external bone and not between the necrotic area and the cranial cavity. Such a case usually goes on to cerebellar abscess.

It is a well-known fact that infection by pre-existing channels as a rule causes meningitis, an exception to this being the aquæductus vestibuli, while if the infection gradually makes its way through the bone the membranes have time to become adherent, and the result is, as a rule, brain abscess. Neumann in 112 cases of cerebellar abscess found 40 to be due to latent labyrinthitis or 43·75 per cent. None of these had been treated by operation for the aural discharge. We can now understand the untoward results got by incomplete operative interference with such cases. Should the radical mastoid operation be performed on a case in which actual suppuration is going on in the labyrinth one of two results will follow, either the infection in the labyrinth will get a fresh impetus and rapidly increasing in strength cause infection of the meninges, or the ear continuing to discharge, at some later date be the cause of brain abscess. We have in such a case added fuel to a fire which might of its own accord have died down, but which now that it has been roused up will go on increasing in strength. As regards those rare cases in which the suppuration in the labyrinth has died down, should the radical mastoid operation be performed this weak spot in the immediate neighbourhood will, in all probability, be infected anew and either meningitis or brain abscess result.

I have endeavoured in this short paper to draw attention to the grave danger of operating on the mastoid before having tested the condition of the labyrinth. The caloric test is simple and easy of application, and all cases, before being submitted to operation, should have this test applied to them. The labyrinth operation can be undertaken with a great degree of safety, and where the labyrinth is found to be affected either by acute suppurative labyrinthitis or latent labyrinthitis, this operation must be performed in addition to the radical mastoid operation. In the lesser degrees of labyrinthine involvement the radical operation should be performed, but a careful watch must be kept on the labyrinth, and should the case progress to the acute suppurative type the labyrinth operation must be undertaken at once. Long-standing cases of chronic middle-ear suppuration should always be examined for latent labyrinthitis. If the caloric test be made a routine practice in all cases such as have been described, then the untoward results after operation will become rare and the number of brain complications from aural suppuration will be greatly decreased.

Glasgow.

# THE PRESENT POSITION OF THE X RAY TREATMENT OF RINGWORM.

BY S. ERNEST DORE, M.D. CANTAB., M.R.C.P. LOND.,
PHYSICIAN IN CHARGE OF THE SKIN DEPARTMENT AT THE EVELINA HOSPITAL FOR SICK CHILDREN, SOUTHWARK BRIDGE ROAD, LONDON, S.E., AND AT THE HAMPSTEAD GENERAL HOSPITAL.

## *The Present Position of the X Ray Treatment of Ringworm.*

OWING to some real and some imaginary dangers attending the use of X rays for ringworm of the scalp doubt has recently been expressed in many quarters as to the advisability of employing a method which is admittedly the only efficient one yet devised for dealing with this intractable disease. A trivial complaint as regards the health of the child, tinea tonsurans brings in its train so long a category of ills that I have more than once heard long-suffering mothers say that they dreaded scarlet fever or pneumonia less. The disorganisation of the home that ensues from the isolation of the sufferers; the anxiety of the parents lest other children in the family should become infected; the complications with medical men and schoolmasters; the social ostracism; the loss of schooling; the wearisome process of constantly rubbing on ointments with little apparent result except the production of sore heads in the children and sore hearts in the parents,—these are some of the difficulties which have to be faced under the old *régime*. Nor is the position of the medical practitioner an enviable one; lack of success in treatment engenders want of confidence—often shared by the relatives of the patient—in his ability to cure the case; certificates of cure are not always preceded by a microscopical examination, and the hasty return of the boy from school leads to recriminations between schoolmaster, school medical officer, local practitioner, and parents. As a last resource a specialist is perhaps consulted; the case may turn out to be one of alopecia areata and expert knowledge is not invariably accompanied by tact, nor will a superfluity of emollients always soothe the troubled waves. Such difficulties as these will still occur, but they are reduced to a minimum when the head is rendered completely bald and therefore free from infection by the X rays, a process of cure which takes a few weeks instead of many months, or even years, when the old methods are employed.

When large numbers of school children are infected with ringworm the question of treatment becomes of national importance from an educational point of view. Unless compulsory preventive measures can be instituted, such as the wearing of some kind of head-gear, like the muzzle in the prophylaxis of rabies, it is essential to employ the quickest possible method of curing the disease, and a strong case must be made out by the conscientious objectors before condemning a method which holds out a hope of stamping it out from the community altogether.

### *London County Council Reports.*

Owing to improved methods of medical inspection in the London County Council schools ringworm now rarely escapes detection, and the results of routine microscopical examination show that its frequency has been much under-estimated in past years. It is a striking commentary on the lack of official recognition of dermatological teaching in the medical

curriculum that in the London County Council returns for 1909 medical certificates that the children were free from ringworm or fit to return to school had been given in 186 cases, but of these ringworm was found in 179 and favus in one, the fungus being absent, or not found, in six only. In the year ending March, 1908, 151 cases were given certificates and ringworm fungus was found in 144 and favus in three, while from April to December, 1908, medical certificates were given in 127 cases where specimens were submitted, ringworm being present in 119 cases and absent only in eight. As regards the relative frequency of the disease 3463 cases were found to be still suffering from ringworm in 1909 (446 of which were treated by Roentgen rays). Of 3019 specimens sent up for examination 2343 were found to be forms of ringworm (comparing with 2175 examined in 1908, of which 1705 were ringworm, and 1578 in 1907, with 1094 showing ringworm fungus).

An organised effort is now being made by the London County Council to cope with the disease. In the report for 1908[1] the recommendations of a special subcommittee (London County Council Report for the two months ended Dec. 31st, 1908) were as follows: 1. That, owing to this obnoxious and contagious disease, many children, estimated at 2950 annually in regular attendance, are prevented from attending school, and expose others to infection at home. 2. That the cure of the disease by lotions and ointments is a process occupying many months, or in some cases even several years, the patient being meanwhile prevented from attending an ordinary school and remaining a source of infection. 3. That the disease is now capable of being cured rapidly by X ray treatment, the child ceasing at once to be a source of infection and able to resume school on the regrowth of its hair. 4. That owing to the fact that X ray treatment is provided only at a few hospitals, where its use is greatly in demand for a variety of adult and other diseases, the treatment is available only to a very limited extent for ringworm cases. 5. That the delay and loss of time suffered by parents seeking, often from a distance, treatment for the children affected frequently results in unwillingness to submit the child for treatment, the child meantime remaining a source of infection 6. That by means of the X ray treatment the disease can be practically stamped out, thus rendering unnecessary the present schools specially maintained for children suffering from it. 7. That provision is desirable for the treatment of the disease by X rays at a fixed centre or centres. 8. That power shall be given to compel the attendance of children for treatment immediately on discovery of the disease.

In the report for the year 1907 it is stated that in 12 schools taken at random in various parts of London 26,766 attendances were lost from ringworm in 12 months. On this basis, the loss of attendance in the whole of London is 1,179,934. Taking the minimum number of sessions in one year required by the Board of Education to be 400, the number of lost attendances is equal to 2950 children in average attendance, or a loss of grant amounting to £5654 per annum. "Evidently," says the report, "there is a financial profit on the treatment of ringworm besides the increased time gained in education." Referring to the X ray treatment of children at Croydon, it was found that the cases are cured in a few weeks and numerous cases given a clean bill of health within the month. It is further stated that there is no doubt that the installation of this treatment will be one of the duties to be attended to in the proposed school clinics, and probably the formation of special ringworm classes will not be required.

The treatment of favus is also considered in these reports, but I do not propose to deal with it except to say that for obvious reasons it is less successful than for ringworm. As favus is almost entirely confined to the alien population it is to be hoped that when proper precautionary measures are taken to prevent the introduction of this and other contagious diseases into the country favus, at any rate, will almost cease to exist.

### *Metropolitan Asylums Board's Reports.*

The efficacy of the X ray method was recognised by the Poor-law authorities by the introduction of this form of treatment into the Metropolitan Asylums Ringworm School in 1905. Before this year the average time during which the child stayed in the school was 19 months; when the X rays were first employed it was reduced to five months, and in 1909 it fell to three and a half months. From the year 1905 to 1908 some 1200 cases were treated by X rays, and about 850 cases in 1909. The number of cases of ringworm admitted at the Downs School during the year 1909 was 947. The corresponding numbers for the years 1903 to 1908[2] were:—

| | | | |
|---|---|---|---|
| 1903 ... ... ... ... ... | 673 | 1906 ... ... ... ... ... | 705 |
| 1904 ... ... ... ... ... | 619 | 1907 ... ... ... ... ... | 748 |
| 1905 ... ... ... ... ... | 619 | 1908 ... ... ... ... ... | 807 |

"This increase has been rendered possible by the efficacy of the X ray treatment, which has resulted in the great diminution in the period of detention of patients."

In 1909 139 children were admitted in excess of the number in 1908, and 241 more were discharged cured than in 1908. Dr. T. Colcott Fox reports that Dr. H. G. Adamson's method of depilating the whole head in five exposures was carried out with success and saving of time. The cases completed were 984 by 2925 exposures, which works out at about three exposures per child. He adds that "we have never observed any ill-effects on the children's health, even in infants."

The report for 1910 is not yet published, but Dr. Colcott Fox tells me that 993 children were successfully treated by X rays without a single instance of permanent baldness. With the exception of a few severe cases of dermatitis when the X rays were first introduced, and a few atrophic patches in subsequent years, cicatricial alopecia has been practically unknown.

### *Results of X Ray Treatment in Paris.*

In Paris the results have been equally striking. Sabouraud states that he has been able to dispense with wards containing 150 beds from the ringworm school which are now being used for other purposes. Reckoning that one bed represents a capital of 10,000 francs, the Assistance Publique has thus made a saving of 1,500,000 francs owing to the introduction of radiotherapy. Up to 1903 the children stayed in the school about two years and there were about 110 cured annually out of 300 pupils. At the present time the treatment requires three months, and 500 children are discharged cured each year, the school being now reduced to 100 beds. The cost for each child during its stay in the school is 260 francs instead of about 2000 francs. Finally, the school will in future be able to accommodate all the cases of ringworm in Paris, including about 350 at the provincial centres. In other words, the Assistance Publique recovered in 1904 a capital of more that 2,500,000 francs, in the shape of 150 beds at the St. Louis Hospital and 350 beds in the provinces. Moreover, it should continue to make a saving of about 400,000 francs per annum by curing five times more cases of ringworm than formerly.[3] According to more recent information, with which Dr. Sabouraud has very kindly furnished me, there are now only 60 to 80 children at the ringworm school, and the Assistance Publique has definitely decided to put the ringworm school at the disposal of the provincial hospitals so that the departments will now send their cases to Paris. Dr. Sabouraud believes that in future there will only be sporadic cases or small epidemics of ringworm in Paris.

### *Risk of Permanent Baldness.*

The old method of treating ringworm is not entirely devoid of risk, for to obtain definite results in a reasonable time it is often necessary to use applications of sufficient strength to set up a certain amount of inflammation around the hair follicles, a process which is occasionally accompanied by scar-formation and the production of small bald patches on the scalp. But it must be admitted that when the X rays are used there is a much greater risk of producing permanent alopecia, and unfortunately there have been a certain number of cases in which failure of regrowth of the hair has occurred. This unfortunate result is partly due to the delicate nature of the method, which requires that a definite dose of sufficient strength to cause epilation be given, failure resulting if the dose falls short of the required amount, while permanent alopecia may ensue if this dose be much exceeded, and partly to the fact that until comparatively recently

[1] For access to this and other reports I am indebted to the kindness of Dr. J. A. H. Brincker.

[2] Annual Report of Metropolitan Asylums Board for the year 1909, pp. 22 and 37.

[3] Dr. R. Sabouraud: Les Taignes, Paris, 1910, pp. 803–805.

there was no reliable means of estimating this epilation dose correctly. The latter difficulty has now been overcome by the use of the Sabouraud-Noiré pastille. If accidents may happen to skilled operators at the present time, it is astonishing, not that they have occurred in the past, but that when cases were treated by fractional doses or even by single doses in a more or less haphazard manner, without the pastille to rely upon, they have been so comparatively few in number.

*Alopecia with Dermatitis.*

Permanent alopecia may occur either with or without preceding dermatitis. The first variety is the one usually met with and is practically always the result of over-exposure. In order to prevent this calamity certain precautions should be taken, the chief of which are as follows:—

*Precautions against over-exposure.*—In the first place, a pastille should always be used, and it must be the pastille of Sabouraud and Noiré; other varieties may have the standard tint too dark or too light and thus constitute a source of danger in themselves.

Secondly, the pastille must be placed in the correct position—viz., exactly midway between the anticathode and the skin, i.e., 7½ cm. from each, in the direct path of the rays, and as near the central rays as possible; it should be placed on a metal surface and be protected from light during the exposure. When taken out for examination, the current should be switched off and the pastille compared with the standard B tint in direct daylight and not in artificial light. It should be replaced as quickly as possible and not be examined too often, since the B tint soon loses its colour when exposed to light.

Thirdly, a tube of medium hardness, which will not become too soft or too hard during the application, should be used. In my experience the best results are obtained from a tube which can be run with the anode kept at a dull red heat, maintaining an alternative spark gap of three to four inches throughout the whole time of the exposure.

Fourthly, a milliampèremeter should be used in the secondary circuit as a control.

*Alopecia without Dermatitis.*

Permanent alopecia without preceding dermatitis is, in my experience, a rare phenomenon, and I have mostly seen it when a first exposure has failed to bring out the hair and a second is given too soon—i.e., less than a month after the first—to the same area. It has also been attributed to the application of strong remedies to the scalp before it is X rayed; to the convexity of the scalp not being allowed for in measuring the distance from the tube, or to movement on the part of the child; to the anode not being accurately centralised, or to the use of an unsuitable tube.

If idiosyncrasy, which has been shown by long experience to be so slight or so rare as to be negligible, be excluded, all these dangers are preventable, and although accidents may always happen, there is no reason why permanent alopecia should occur if reasonable care and judgment be observed on the part of the operator.

*Pustular Dermatitis.*

A pustular dermatitis of the scalp resulting from pyogenic infection is a very troublesome complication in hospital practice. Its frequency and severity are doubtless in part due to the lowered resistance of the scalp brought about by the action of the rays, and it can only be prevented by strict attention to cleanliness and the application of a weak antiseptic lotion or ointment before and after exposure. The wearing of a tightly-fitting linen cap, fastened on by a tape or elastic under the chin, day and night is a useful precaution. This pustular dermatitis, however, is usually superficial and yields to antiseptic remedies. It is not often a cause of baldness *per se*.

*Recovery of Growth of Hair.*

With regard to recovery of growth of the hair, Sabouraud contends that, although regrowth may be delayed by a slightly excessive dose, if new hair has not made its appearance in six months after depilation the patch will be permanently bald. This is no doubt true of severe cases, but I have seen considerable improvement in atrophic patches after this period of time, and know of one case in which I am told on good authority that complete recovery took place after 12 months.

*Risk of Injury to the Brain.*

I have endeavoured to show how the only real danger of the X ray treatment of ringworm—viz., the production of permanent alopecia—can be avoided. The danger of injury to the brain, if not merely hypothetical, as I believe it to be, is a far more serious matter than injury to the scalp alone. It has given rise to much discussion amongst workers in the subject as well as to many alarmist statements in the lay press. No doubt the publicity given to the injuries sustained by some radiographers, who have exposed themselves to the X rays for prolonged periods, often without adequate precautions, has had a large share in discrediting the use of X rays as a therapeutic measure. This, however, has no bearing upon the point under discussion, for no radiographer, as far as I am aware, has ever suffered any mental or cerebral injury from the rays. On the other hand, there are certain facts which make a close examination of the hypothesis not only advisable but imperative.

Radiograms show that X rays have little difficulty in penetrating the bones of the skull; nervous phenomena and pathological changes in nervous structures have been experimentally produced in small animals, and a few cases of nervous symptoms in children following X ray exposures have been recorded. It may be argued that a photographic plate is not the same as the cells of the human body; that large experimental doses given to small animals are not the same as therapeutic exposures given to children; and that such symptoms as have occurred in children—e.g., sleeplessness, headache, &c.—are more likely to be the result of the mental excitement caused by the operation than of any distinct effect on the brain substance; but the strongest argument undoubtedly rests in the absence of positive clinical evidence of harmful effects and the enormous numbers of children treated during the past five years, with absolutely negative results as regards the production of any symptoms of cerebral injury.

*Sabouraud's Results.*

Sabouraud states that since the end of the year 1903 he has been able to see and follow up every year in hospital alone an average of 500 children, varying in age from 2 to 15 years, who have been treated for tinea tonsurans by X rays. In no case has he been able to observe either cerebral trouble, or even any retardation of intellect, following the application of the X rays, and as the children under treatment continue their classes any intellectual change would be easily perceptible in them. In 17 cases idiots, epileptics, or backward children were treated and no modifications were observed.

Formerly Sabouraud refused to submit children of 2 years to the X rays for fear of possible accidents owing to the large fontanelle being imperfectly ossified. But since a rachitic child was inadvertently treated without any nervous reaction following after six months' observation, children of 2 years have been X rayed and always without accident. Even in cases where a double dose has been given by mistake no cerebral phenomena have ever developed.[4] I have already quoted Dr. Colcott Fox's opinion on this subject, and Dr. Adamson is in agreement with him.

In an exhaustive paper on the X Ray Treatment of Ringworm of the Scalp[5] Dr. J. M. H. MacLeod gives his experience of 370 children treated up to May, 1909. He was unable to obtain any evidence of injury to the brain from his own cases, from the literature on the subject, or from anyone with experience of the treatment whom he asked. His experiments, which I shall refer to later, also strongly negatived the possibility of any such injury occurring.

At the meeting of the British Medical Association at Belfast in July, 1909,[6] Dr. Sequeira said that he had treated 1400 cases by the pastille method and considered risk of injury to the brain purely imaginary. 267 of his cases had come from institutions where they were under expert examination of both medical officers and school teachers. From them he had had a report that in no single instance was there, after several years' interval, the slightest evidence of any delayed development or other injury to the brain.

From my own experience of the results of the X ray treatment in over 2000 children in hospital practice and private

[4] Dr. Sabouraud: Annales de Dermatologie et de Syphilologie, vol. x., 1909, pp. 452-461.

[5] Dr. MacLeod: THE LANCET, May 15th, 1909, pp. 1372-1377.

[6] THE LANCET, August 14th, 1909, p. 468; and Brit. Med. Jour., August 21st, 1909, p. 654.

practice, I am able to confirm these statements in every particular. I have met with a few instances in which irritability, headache, and sleeplessness occurred soon after treatment. In one case in which persistent headache developed after the first few exposures, the symptoms did not recur when the applications were repeated, and in the others they were transitory and more easily accounted for on other grounds.

In a series of 50 cases sent to me from an institution for treatment by X rays I had one case of permanent alopecia; this was in a boy treated in 1906 without a pastille, in whom three exposures failed to cause epilation, and a fourth caused a vesicating dermatitis, followed by a bald patch of about the size of a five-shilling piece. These cases were treated between the year 1905 and 1909, both by the multiple and single exposure methods. The children have all been kept under observation since, and I have recently been informed that in all of them, with the exception of the one just mentioned, the hair has grown as well as or better than before, and that none has shown any indication of delayed physical or mental development or other deleterious effect referable to the X rays.

*Experimental Evidence.*

Experimental evidence of the quantity of rays passing through the scalp and bone during a pastille dose of X rays has been provided by Dr. MacLeod,[7] by Mr. R. Higham Cooper, and by Dr. Sidney Russ and Dr. Henry MacCormac, working in the Cancer Research Department of the Middlesex Hospital. Dr. MacLeod placed a piece of the thinnest portion of the parietal bone of a child's skull and a piece of fresh scalp in front of a Sabouraud pastille exposed at 7½ and at 15 cm. from the anticathode. He found that the bone absorbed 50 per cent., and the scalp approximately 30 per cent. of the rays, leaving 20 per cent., or one-fifth, of a pastille dose to enter the brain. In these experiments no allowance was made for the resistance of the meninges nor for the distance between the surface and centre of the brain. He came to the conclusion that the scalp and meninges so protect the underlying brain that only a very small proportion of X rays, if any, can reach it, and that this small proportion instead of doing harm may even act as a stimulant.

Mr. Cooper[8] found that the effect of a single dose on the cortex immediately beneath the meninges was about one-twentieth of a pastille dose. He also devised an experiment to show the effect of the rays which converged on the base of the brain during a total epilation. The experiment consisted in the introduction of a pastille through the foramen magnum of the dried skull of a child aged 5 years, the skull being exposed as in a case of total epilation. The pastille was turned to face the incident rays at each exposure. A screen of cardboard, coated with white lead until it offered the same resistance to the rays as a piece of fresh child's scalp, was placed on the skull. The number of exposures given to represent a complete epilatory dose was eight, but in the experiment 75 pastille doses were required—equivalent to nine and a half total epilations—before tint B was reached. Allowing for the increased distance of the experimental pastille from the tube, it was calculated that without allowing for the additional resistance of the brain itself and its vascular membranes the portion of the brain in the situation of the pastille within the skull would receive one-ninth of a Sabouraud dose during treatment of the whole scalp. He concluded that there was no risk of injury to the brain, and when Sabouraud's instructions were followed very little risk of injury to the scalp, and further, that even this risk would disappear with improved apparatus, especially as regards regulation of the vacuum of the tube.

Dr. Russ and Dr. MacCormac have adopted a more scientific method of measuring the rays by means of the electroscope, and, although their work is as yet unpublished, they have kindly allowed me to state that for a given specimen they find that 20 per cent. penetrates the scalp and skull.

*The Kienböck-Adamson Method of Treatment.*

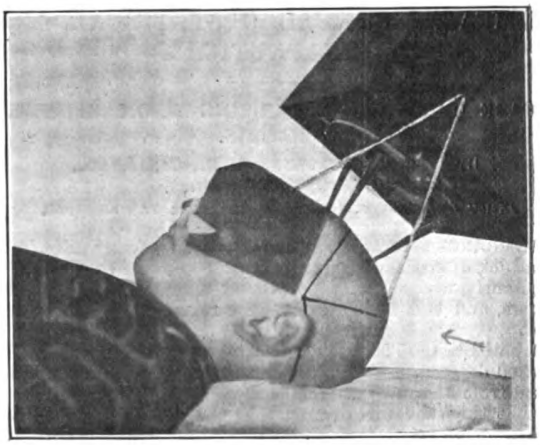
The old plan of giving multiple fractional doses has now, chiefly owing to the use of the Sabouraud pastille, been superseded by that of epilating a single patch in one exposure. Sabouraud's method for total epilation consists in covering each patch, after it has been exposed, with a disc of lead, the discs overlapping so that no fringes of hair remain. Eight or nine exposures are required for a head of average size.

The method which I have found superior to all others, both in efficiency and in the saving of time, is that first suggested by Kienböck, and subsequently elaborated and applied to the treatment of ringworm by Adamson.[9] The tube is placed in a box having an aperture of not less than 3 inches diameter for the passage of the rays, three wooden pegs project from the circumference of the aperture, so that the tube is at the correct distance when they rest on the scalp. The child's hair having been clipped short, the scalp is marked out as shown in the illustration, kindly lent me by Dr. Adamson (who took the photographs), five equidistant points being taken as a centre for

FIG. 1.

Showing scalp marked out for exposure of the whole scalp.

FIG. 2.



Showing the head in position for X-raying the front part of the scalp—position No. 1. The white lines indicate the cone of rays. The arrow indicates the direction in which the second dose—that to the back part of the crown—is aimed.

each exposure. Allowing 15 minutes as an average exposure (shorter exposures do not allow sufficient margin for slight errors of dosage) the whole scalp can be treated, either in one sitting or on successive days, in one hour and a half. The hair begins to fall as usual on the fourteenth or fifteenth day; in three weeks the child is quite bald and free from infection, new hair appears in about six weeks, and in three months the scalp is well covered. When fully grown the new hair is often thicker in texture and slightly darker in colour than the old, and is occasionally curly instead of straight. On account of the overlapping and the large size of the areas treated there is less likelihood of small patches of hair being left, and the risk of reinfection is thereby minimised. The

[8] Mr. R. Higham Cooper: THE LANCET, August 14th, 1909, p. 467; British Journal of Dermatology, December, 1909, p. 391.

[9] THE LANCET, May 15th, 1909, pp. 1378–1380.

danger of giving marginal areas a double dose is also avoided. The fact that the whole of the scalp is usually exposed is no objection; experience shows that partial epilation is often worse than useless in hospital cases, and that total epilation should nearly always be insisted upon. Since I adopted this method in private practice a year ago and at the Evelina Hospital, where more than a hundred complete cases have been treated under the supervision of Mr. Cooper during the past nine months, the results have not only been more satisfactory than before, but the saving of time has enabled a larger number of hospital cases to be dealt with without any increase of risk to the children.

In conclusion, there are two points upon which I would lay stress. In the first place, if the X ray treatment is to be successful, it must be conducted in a methodical and systematic manner, by a trained operator and under skilled supervision; the child's head should be carefully and accurately marked out with a blue pencil before the treatment is begun, and the patient and apparatus should be watched during the whole time the child is under the rays. Secondly, the operator must not be stinted as regards efficient tubes and apparatus; the excessive use of one tube is false economy and may be dangerous, and such appliances as the milliampèremeter for measuring the current in the secondary, the valve-tube for checking the reverse current, the spark-gap for testing the resistance of the tube, &c., are additional safeguards.

The cases of permanent baldness I have seen have been, for the most part, due to the employment of an unskilled or careless operator or to the use of unsuitable tubes. But it is almost impossible to expect uniformly satisfactory results in the present crowded state of the electrical departments of the few London hospitals able or willing to undertake the X ray treatment, and it is a matter of urgent necessity that better provision shall be made for dealing with these cases in the future.

### A CASE OF DEAFNESS ARISING FROM EPIDEMIC PAROTITIS.

BY LINDLEY SEWELL, M.B., B.S. LOND., M.R.C.S. ENG., &c.,
ASSISTANT SURGEON TO THE MANCHESTER EAR HOSPITAL.

ALTHOUGH the fact that serious deafness may arise from an attack of epidemic parotitis is well known to aurists, it is apparently not so well appreciated among general practitioners, and this is my excuse for reporting the following case.

A patient, aged 36 years, came to see me complaining of marked deafness and tinnitus on the right side. The trouble dated from an attack of mumps three months previously, and at that time she was assured that the deafness she noticed was transitory and was merely due to catarrhal swelling of her Eustachian tubes. She had for a few days marked dizziness and an inclination to vomit. On examination the tympanic membrane had a normal appearance. The akoumeter was heard at a distance of 3 inches; and, excluding the sound ear by means of Bárány's noise apparatus, the spoken voice was heard at about a distance of 3 feet. Using tuning-forks ranging from C 64 to C 2048 it was found that the hearing power by aerial conduction was markedly diminished at the upper end of the scale. The time during which tuning fork C 128 placed on the mastoid region was perceived was diminished by 14 seconds. Rinne's test was positive, and Weber's was lateralised to the opposite and sound ear. On using the catheter the Eustachian tube was found to be patent, and no change in the hearing was induced by inflation. She was slightly unsteady in her gait, stumbling to the right. There was no nystagmus. Under a course of strychnine in increasing doses and small doses of quinine sulphate the dizziness disappeared, but there was no improvement in the hearing power and but little diminution in the tinnitus was effected.

I had a similar case two years ago, the notes of which have been unfortunately lost. In both cases the deafness was regarded at first as trivial; in both cases irremedial damage had occurred to the internal ear. The exact nature of the pathological change is imperfectly understood at present. The treatment advised is to institute injections of pilocarpine as soon as possible after the onset of the condition; and, indeed, in the early recognition of the trouble and the prompt employment of pilocarpine lies the only hope of bringing about any improvement. It must at once be admitted that in the majority of cases, even in spite of the early use of this drug, no change in the deafness is procured. From the point of view of prognosis it is important to realise that in most cases the deafness arising from epidemic parotitis is of a serious nature and that the outlook is generally unfavourable.

Manchester.

### NOTE ON A CASE OF FOREIGN BODY IN THE URINARY BLADDER.

BY H. W. WEBBER, M.S. LOND.,
SURGEON TO THE SOUTH DEVON AND EAST CORNWALL HOSPITAL.

A BOY, aged 14 years, was admitted to hospital on Dec. 17th, 1910, with the following history. On the 16th he sat on something sharp which penetrated the perineum; inquiry disclosed that a pointed piece of slate-pencil "found itself" point upwards on the seat, whether accidentally or otherwise was not clear. He was immediately taken to a medical man, who found the wound of entrance in the right ischio-rectal fossa, and under an anæsthetic enlarged the wound and searched for the foreign body. It could be felt, but could not be removed, and the boy was sent into the hospital. On admission a radiograph was taken, and the piece of pencil was seen to be lying transversely in the centre of the pelvis, the radiographist, Dr. W. Cheyne Wilson, expressing the opinion that it was in the cavity of the bladder. Accordingly, on the 19th the patient was anæsthetised and sounded, the foreign body being distinctly felt and heard. A median perineal cystotomy was performed and the pencil found wholly in the bladder, lying transversely and wedged by its ends. On extraction it was found to be a piece of well-sharpened slate-pencil, 2½ inches in length. Recovery was rapid.

### CLINICAL SECTION.

*Exhibition of Cases.*

A MEETING of this section was held on Feb. 10th, Sir ALFRED PEARCE GOULD being in the chair.

Dr. H. D. ROLLESTON and Dr. C. H. S. TAYLOR showed a case of Mollities Ossium of 45 Years' Duration. The patient was a single woman, aged 58 years, for years a patient of Dr. H. Hollis in the Wellingborough Workhouse, who had been bedridden for 44 years on account of inability to walk and bony deformities which at first suggested rickets, but, as shown by the X rays, resembled those of mollities ossium. She was not strong as a child and did not begin to walk until three years of age, thus suggesting rickets. Between her fourth and fifth years the right knee began to bend outwards, but until 13 years of age she was able to walk, though clumsily. At the age of 11 she had whooping-cough, and at 13 "inflammation of the bowels." Her mother connected the osseous changes with the whooping-cough. At the age of 13 her strength began to fail, walking tired her, and she took to bed, where had remained since. She ached all over, and her teeth began to decay and were all gone when she was 37. Since the onset the bony deformity had gradually increased, but was most progressive at the time she first took to bed. There was no history

of any bony fracture, but she had pain in the left lower ribs at the age of 13. Menstruation began at 15 and stopped at 45. Pubic hair appeared before the age of 15. When held up—for she cannot stand—her height is 45 inches. The forehead is prominent, and the circumference of the head is 21½ inches. The rotation of the head is somewhat restricted and the sterno-mastoids are shortened and contracted. The distance from the suprasternal notch to the symphysis pubis is 14½ inches. The spinal column shows a continuous curve forwards in the dorsal and cervical regions, and there is scoliosis to the right in the dorsal region. The thorax shows lateral flattening, and the respiratory movements are mainly abdominal. There is considerable thickening in the outer curvature of each clavicle. The upper extremities are more deformed than the lower, and in that connexion it might be mentioned that she had never used crutches. The right upper extremity is more affected that the left. Each humerus shows an antero-external curvature which is most marked in the upper third; the muscles are stretched across the curves formed by the humeri. The movements at the shoulder-joints, especially the right, are somewhat restricted. The right forearm cannot be completely extended, but flexion is perfect. The right radius is twisted round the ulna at its lower end, supination and pronation are restricted. At the wrists extension is prevented, but flexion is good. The hands are fairly normal and can be used for sewing. There is no clubbing of the fingers. The patient cannot stand, and when supported rests on the toes; when the heels are placed on the ground she collapses towards the left. The thighs can be flexed at the hip to a right angle, but abduction and adduction are limited. The femurs, especially the right, are curved with the convexity forwards and slightly outwards. At the knee-joints the tibiæ form an obtuse angle with the femur, thus to some extent resembling Mr. Clinton T. Dent's case of "double displacement backwards of the tibiæ, with deformity of the long bones and arrested development." To the outer side of the right ligamentum patellæ there is what appears to be a loose body in the joint. The legs cannot be completely extended at the knees, but can be flexed fairly well. The tibiæ and fibulæ present a concavity to the right. The left ankle can be extended to a considerable degree, but cannot be flexed to more than a right angle; the movements of the right ankle are not quite so good. The patient did not show any evidence of infantilism and was normal mentally. The thyroid could not be felt. The urine contained a trace of albumin. The maximum systolic arterial blood pressure was 100 mm. Hg; the viscera were otherwise normal. She weighed 4 stones 11 pounds. On Feb. 6th, 1911, the blood count was as follows: red cells, 4,045,000 per cubic millimetre; white cells, 10,400 per cubic millimetre; hæmoglobin, 95 per cent.; colour index, 1·18; polymorphonuclear cells, 75 per cent.; lymphocytes, 23 per cent.; mononuclear cells, 2 per cent.; eosinophile and mast cells, none seen; red cells, normal. When first seen the condition was thought, on the bases of appearances and history, to show the results of late or recrudescent rickets. Dr. G. Allpress Simmons's X ray examination showed that the changes characteristic of rickets were absent and that the appearances pointed to mollities ossium. As they were uncertain about the occurrence of real arrest in mollities ossium, which such a long duration suggested, Dr. Rolleston and Dr. Taylor obtained the help of Mr. Dent, who kindly referred them to the account of his case already mentioned, and also to his unpublished Hunterian lecture at the Royal College of Surgeons of England in 1905. In his first case, published in 1882, a condition very similar to that in the present patient followed scarlet fever; in that paper he mentioned records and specimens of cure or arrest of mollities ossium. In his Hunterian lecture he explained the osseous softening as a result of the action of pathogenic organisms on the bones; he also referred to four or five cases under his observation in which softening of the skeleton, followed after a long interval by recovery of the rigidity of the bones—but in a condition of great deformity—apparently dated from an attack of whooping-cough. He quoted Siegert, who collected four cases of mollities ossium occurring at the ages of 10 years, 10 years, 13 years, and 16 years in children who had all had, but recovered from, rickets. The present case, which appeared to belong to that category, raised the interesting question if many or most of those cases formerly recorded as "late rickets" were really examples of osseous softening due to some microbic invasion of the skeleton and not to rickets in the strict sense. Siegert's cases and their case suggested that ordinary rickets, by damaging the skeleton, might favour the onset of mollities ossium.—Dr. ALLPRESS SIMMONS said that the bones generally were very translucent and light in texture; the shafts of the long bones were thin, the compact layer narrow, and the central canal disproportionately wide. The extremities were expanded in proportion to the shafts, very light in texture, and did not appear more opaque at the periphery as compared with the centre. The absence of the compact layer in some cases extended from the extremities for some distance along the shafts. The articular surfaces generally were clean cut and normal, and there was no lipping of the articular edges. The skull bones, as far as seen on the skiagram, were of normal thickness; the base of the skull appeared to project abnormally upwards into the cranial cavity. The jaws were edentulous except for an unerupted upper back tooth. The bodies of the vertebræ were vertically compressed, and the absence of definite light spaces between them suggested either that intervertebral fibro-cartilages were very thin or that they were infiltrated with lime salts or both. There was a slight forward convexity of the upper cervical spine; there were four lateral curves in the spine—namely, a convexity to the right, opposite first dorsal vertebræ; to the left, opposite seventh and eighth dorsal vertebræ; to the right, opposite the eleventh rib; and to the left in the lower lumbar region. The pelvis was compressed from above down opposite the sacral promontory and laterally upwards and inwards on both sides opposite the hip-joints, its cavity being thus converted into a sharp trefoil shape. The left ribs looked fairly normal. The fourth, fifth, sixth, and seventh right ribs had a sharp inward convexity at about mid-distance, with a boss at that point strongly suggestive of a repaired fracture. With regard to the left upper extremity, the clavicle was fairly normal, as was also the scapula. The humerus had a general slight inward convexity and had fusiform thickenings at about the junction of the upper and middle and middle and lower thirds, and at those points the ordinary extra thin compact layer became abnormally thick. The left radius and ulna were fairly normal in appearance. The right clavicle had a bossy expansion at about the junction of the mid and outer thirds. The right scapula had its axillary border abnormally thick, especially at a point about two-thirds down. The right humerus had a complicated U-shaped bend at about a junction of the mid and lower thirds, the general direction of which was concave, inwards and forwards. The compact layer was somewhat thicker on the convexity than on the concavity of the bend, and there was no sign at any of the bends-in or bosses on the bones of any sustaining buttresses in the concavities of the bends or of any threatening or old fractures, with the exception of the ribs mentioned already. The right radius and ulna had a U-shaped bend with the concavity inwards at about the mid-point. There was no marked deformity of the bones of the hands. The neck of the left femur was short and thick, and its upper surface was encroached upon by the expanded and bossy great trochanter; the lesser trochanter was upwardly and inwardly hooked. The shaft had a general outward convexity; the lower end of the shaft was sharply implanted into the expanded condylar portion, very much like the stalk of a flower. The double contour seen on the inner aspect of the left femur was caused by a muscle shadow and was not due to bone. The neck of the right femur was somewhat longer than that of the left, and its upper surface was encroached upon by the expanded and bossy great trochanter, as on the left side; the lesser trochanter also had an upward hook. There was a very well-marked inward bend at the junction of the head and neck. The shaft of the right femur had a double lateral curve, of which the upper was curved outwards, the centre of curvature being at about the junction of the upper and middle thirds, while the lower two-thirds of the bone had a general inward convexity. The left fibula was straight; the left tibia had a marked forward convexity with the centre of the curvature at about the junction of the mid- and lower thirds. The right tibia and fibula were fairly straight, having only a slight forward convexity. The ankle-joints and joints generally of the feet looked normal, the only marked deformity of bone being some flattening of the inferior surface of the right calcaneum. In summing up Dr. Simmons said

that the deformities generally suggested that the bones were slightly plastic, and they bent therefore in proportion to the stresses upon them. Thus, the long bones, which were subject to unequal stresses, showed most bending; the pelvis showed the effects of weight, while the hands and feet, which had few internal stresses, showed hardly any deformity; and the skull, which had practically no muscle pulls upon it, retained its shape except where its weight caused it to sag, as it were, around its base.

Dr. FREDERICK J. POYNTON showed a case of Imperfect Osteogenesis. The patient was a female, aged eight years, the second of four children; the other three had no signs of the condition. The parents were German Jews. The child had been under observation for six years. There was a history of soft bones at birth and fracture at 14 days. From that time there had been fractures of all the long bones at intervals, usually results of slight injuries. There had never been well-marked evidences of rickets or congenital syphilis. The child was bright and intelligent, but had never been able to walk. The course of the case was in accord with that usually found in the disease, but there were a few interesting points. One of those was that the disease seemed to be arrested some two years ago, and as the child was hopelessly crippled by the terrible distortion of the lower extremities both legs were put in excellent position by Mr. Kellock. Union followed, and the limbs were much improved. The present condition illustrated the ultimate result. He believed there was in that case, as in some others he had had under his care, an element of neglect by the parents, and no real pains were taken to keep the child's limbs from injury. A third point was the history of the development of the lateral bosses on the skull. Those followed a fall and commenced as large cephalhæmatomata. Prognathism was present. During the last 12 months the child had become thinner and there was slight pyrexia, which was apparently not infrequent in the disease. Many methods of treatment had been tried but without any obvious result. The salient deformities were: (1) bosses immediately about the ears on either side; (2) prognathism; (3) diminution in the vertical and widening in the lateral and antero-posterior diameters of the chest; (4) spinal lordosis; (5) left clavicle, old fracture; (6) right humerus, radius and ulna, old fractures; (7) right femur fractured and bent; (8) right fibula and tibia fractured, the child's foot rests on its inner side upon the bed; and (9) left femur, tibia, and fibula fractured and bent. All the long bones were exceedingly small.

Mr. A. J. WALTON showed a case of Imperfect Osteogenesis (?) for Mr. FRANK S. KIDD. The patient was a boy, aged 7, who was sent up to the London Hospital by Mr. G. Aldridge of Sheerness. At the age of three the boy fell and broke his right femur and was admitted to Chatham Hospital, where he remained seven and a half months. A large swelling developed at the site of the fracture and a diagnosis of sarcoma was made, but the father refused operation and took the boy to see Mr. W. H. Battle at St. Thomas's Hospital. The lower half of both legs became gradually bent into their present position. Two years ago the right forearm was broken by a fall. Two months ago the left upper arm was broken and set. When the splints were removed the present swelling was noted. The child had been bottled-fed and had had a patent barley. There were four children in the family; two were healthy. One other boy had a leg amputated for a similar condition and had had several fractures. The general condition was excellent; nothing abnormal was shown by the temperature chart. The urine was acid, of specific gravity 1020; there was no albumin, albumose, or sugar. The bones of the skull and face, teeth, clavicles (?), ribs, sternum, and vertebræ appeared to be healthy. The fontanelles were closed. There was no rickety rosary. The shape of the chest was normal. The left humerus had a fusiform swelling at the lower end of the bone of bony hardness. There was no pulsation or crackling to be felt in the swelling, which expanded the bone equally all round. The fracture had united. The maximum circumference of the swelling was 9½ inches. The skiagram showed a fracture in the middle of the shaft and a mass of irregularly trabeculated new bone between the fractured ends, under the periosteum of the shaft, and in the flexor muscles in front, but a large part of the swelling threw no bony shadow, though it felt of bony hardness. The extreme lower end of the humerus showed an area of central resorption of bone extending an inch up the shaft. The left forearm showed a bend in the middle of the radius and ulna. The skiagram seemed to indicate an old fracture at that level. The radius and ulna threw very faint shadows on the plate—evidence of deficient ossification. On the right forearm both bones were bent backwards, the radius about its middle, the ulna nearer its lower end. The skiagram suggested that a fracture had occurred at those levels, with deposit of periosteal callus. On the right femur there was a fusiform swelling extending the whole length of the bone, which was of bony consistency and did not pulsate. The maximum circumference was 11½ inches. The skiagram showed that the whole shaft of the bone had been expanded, and the trabeculæ had been rearranged as a wide-meshed cancellous tissue, as though the bone were filled with numerous cysts. The skiagram showed that the shaft of the right femur was bent outwards, and that at the lower end of the bone there was resorption of bony tissue with rearrangement of the trabeculæ as a wide-meshed, irregular network. That change was also to be seen in the lower epiphysis. The epiphyseal line appeared to be normal. In the upper end of the bone the normal lamellar arrangement was well shown. The appearance of the legs below the knees could be seen in the skiagrams. The tarsal bones showed a cyst-like arrangement of the trabeculæ similar to that seen in the right femur, and to a less extent in small patches in the following positions: the lower epiphysis of the right fibula, the upper end of the left tibia, the upper end of the right radius, the lower end of the left femur, parts of the pelvic bones, the glenoid portion of the left scapula, the upper ends of each humerus, and the bones around the left elbow-joint. The swellings had not altered in size during the three weeks the child had been under observation.

Dr. H. BATTY SHAW showed pictures of two cases with unusual Ulceration of the Skin. The first case showed icteric ulcers of the legs in hepato-splenomegaly. The patient was a man, aged 28 years, who had been icteric for 23 years. Urobilin was present in the urine, but no bile; the spleen especially and the liver were enlarged. He was liable to recurrent attacks of increased icterus, but of late years the attacks were less frequent. He had two ulcers, one on the outer malleolus of the right foot and one on the inner aspect of the left one; they began 15 years ago. The ulcers healed when the patient rested in bed, but broke down again on resuming ordinary life. The skin in the neighbourhood was discoloured reddish-purple. There was slight enlargement of the veins of the neighbourhood, but no varicosity. The case was shown before the Clinical Society in 1902; the icterus was in existence then. The second case showed icteric ulcers of the legs in pernicious anæmia. The patient was a woman, aged 42 years, who had had abdominal pain and vomiting for the last two years; during the same period she had been noticed to be yellow. The catamenia had always been irregular, and amenorrhœa had existed for two years. Amongst the past illnesses there were measles and whooping-cough, "inflammation of the lungs" ten years ago; quinsy five years ago. At the ages of 12 and 22 years she had had attacks of abdominal pain and vomiting similar to the present attack. She was only fairly well nourished and was very weakly. There were systolic murmurs at the apex beat of the heart and at the pulmonary cartilage; the pulse (90 to 100) was regular but of low tension (90 millimetres). There was much pyorrhœa alveolaris and the gums occasionally bled; the tongue, though pale, was otherwise normal. The liver reached two fingers' breadth below the costal margin; the splenic area of dulness was increased; the right kidney could be felt. During her stay in hospital the temperature rose from normal to 101·8° F. There was some constipation. The urine, examined seven times, always showed a faint cloud of albumin; it was pale and contained a slight excess of urobilin, no bile. The skin and conjunctivæ were lemon-tinted. The serum showed the presence of a slight amount of bile and of urobilin. The fundi oculorum were normal. A blood examination was carried out on two occasions and each time showed marked anisocytosis, poikilocytosis, and vacuolation of the red cells; megalocytes preponderated; no nucleated red cells were seen. An analysis on Jan. 18th last showed: total red cells, 935,000 per cubic millimetre; hæmoglobin, 30 per cent.;

colour index, 1·45; total white cells, 3850 per cubic millimetre; small lymphocytes, 56 per cent.; large lymphocytes, 25 per cent.; polymorphonuclear cells, 19 per cent. On the 25th it was as follows: total red cells, 1,225,000 per cubic millimetre; hæmoglobin, 30 per cent.; colour index, 1·10; total white cells, 6500 per cubic millimetre; small lymphocytes, 19 per cent.; large lymphocytes, 18 per cent.; hyaline cells, 4 per cent.; polymorphonuclear cells, 58 per cent.; and transitional cells, 1 per cent. During the last four days in the hospital the patient became mentally disturbed, developing delusions and becoming maniacal. She was allowed to go home. The development of the icteric ulcers began simultaneously six years ago as "blisters containing blood," which broke and left small ulcers. Those were present in the neighbourhood of each internal malleolus and were irregular in shape and shallow; the surrounding skin was purplish-red and a little indurated. The ulcers did not cause pain and appeared to be independent of any varicosity of the crural veins, which were normal in size and appearance. There was no history of an injury which might have caused them to develop, and there was no specific history.

Dr. BATTY SHAW also showed a case of syphilis, chyliform ascites, dropsy, and albuminuria. The patient was a man aged 28 years, who had contracted syphilis 18 months before admission to hospital, and was treated with pills containing mercury for over 12 months. Other than what appeared to have been an attack of "peritonitis" three years ago (which was recovered from in 14 days), there was no history of other antecedent illness. Two months ago his legs and abdomen began to swell; abdominal pains began, and the urine was much reduced in amount, was turbid, and was found to contain albumin; diarrhœa began at the same time and lasted three weeks. The abdominal pain was so severe as to prevent sleep. He was tapped by his local medical attendant, and on each occasion several pints of opalescent fluid were removed. On admission to hospital he was found to have ascites, and dropsy was present in the legs, sacrum, and lower back. That had persisted during his month's stay in the hospital. The temperature was over 99° F. for about 14 days and then become normal. The urine contained hyaline and granular casts; albumin was always present, varying from a total of 3 grammes to 32 grammes in the 24 hours (Esbach), the quantity of urine from 21 ounces to 100 ounces. He was tapped on two occasions and the ascitic fluid was opalescent each time and found to contain no free fat. Wassermann's reaction in the blood was positive, and an atypical spirochæta was found in the urine; the ascitic fluid did not reveal the spirochæta pallida, but gave a positive Wassermann's reaction. Half a gramme of salvarsan was injected subcutaneously on Jan. 12th and on the 14th the blood gave a negative Wassermann's reaction. Neither the ascites and dropsy nor albuminuria appeared to be influenced favourably or unfavourably by the injection, as the patient's condition on leaving the hospital was much the same as on admission. On the occasion of the present demonstration—i.e., one week after leaving the hospital—there was no trace of ascites, the liver edge could be felt below the right costal margin, and a fairly well-marked show of albumin was present in the urine.

Dr. J. D. ROLLESTON and Dr. N. S. MACNAUGHTAN communicated a report on a Tumour of the Upper Lip shown at the last meeting of the section. The tumour, which was removed by Mr. P. L. Daniel on Jan. 25th last, was found to consist of a mass of solid convoluted cords embedded in fatty and fibrous tissue, and to be attached by a pedicle to the right infra-orbital nerve, thus presenting macroscopically the appearance of a plexiform neuroma.

Dr. F. E. BATTEN showed a case of Progressive Spinal Muscular Atrophy of Infants (Werdnig-Hoffmann). The patient was a girl, aged 1 year and 9 months, the second of two children, the mother and father being healthy. The first child, a boy, died at the age of 8 months from bronchopneumonia. He was said to have been very loose in the limbs from the time of birth. The patient was born at the seventh month and was delicate for four months. She was said to kick about a good deal up to six months old, and appeared fat and healthy. When six months old she was vaccinated and cut her first tooth. She was said to be able to sit up at seven months, but was not encouraged to do so. At seven months she was able to talk a few words. Since she was 7 months old she had gradually become weaker and more helpless, and that weakness was said to have increased since October, 1910, and she could not now lift her head off the pillow. She was seen as an outpatient in June, 1910, by Dr. Gordon Holmes. She was then unable to sit up and had weakness of the back; she could make no attempt to stand. All the deep reflexes were absent. The Mongoloid appearance of the child was noticed. She was placed on thyroid half a gramme twice a day and improved, and was noted as "much improved" in October, 1910. The bowels had been constipated. She took food well, and as she lay in bed appeared quite healthy. The child was fairly nourished. She was happy and contented, said little words, and took notice of all that went on. She heard and saw well, and as far as was possible obeyed commands. The palpebral fissure was small and oval, and that gave her the appearance described as "Mongoloid," but there was no obliquity of the eyebrows outward, the skin was quite soft, the head of normal size, and the tongue smooth, so that there was nothing to suggest the child was a Mongolian idiot, though the term "Mongoloid" was justified. The incisors, canines, and first molar teeth were all present. The movements of the eyes, tongue, jaw, and lips were normal. The optic discs were normal. There was nothing wrong with the heart, lungs, or abdominal viscera. The chest was long and narrow, and on inspiration the intercostal spaces sank in, and it was clear that respiration was carried on by the diaphragm alone, which acted vigorously. The abdominal muscles were weak but not completely paralysed. If the child were placed in a sitting position the head fell forward, backward, or sideways, the neck muscles being powerless, the back became bent, and there was no power in the trunk muscles either to flex or to straighten the back. When placed flat on the bed, however, the spine was perfectly straight. The arms lay, as a rule, flexed at the side of the chest; the child could make little movements with the fingers and could grasp objects feebly. She could just flex the elbow and pronate, but not supinate the hand. The forearms were more or less fixed in a position of pronation. There was no power of movement in the shoulder muscles. The legs were almost powerless; there was practically no power of flexion of the hips or knees, but there was a little power in flexion and extension of the ankle and toes. The ham-strings were contracted so that the right leg could not be fully extended. The limbs were thin and the muscles were wasted, but that wasting was to a considerable extent covered up by the subcutaneous fat. The loss of tone in the muscles was very considerable, but the feet could not be flexed over the shoulders, nor could the arms be crossed behind the child's back, positions which were possible when the hypotonia was marked in a child. Sensation to ordinary stimuli appeared unimpaired all over the body. The knee-jerks, ankle-jerks, and all the deep reflexes were absent. The abdominal reflexes and plantar reflexes could not be obtained. The sphincter ani was normal. The electric reaction showed complete loss of response to faradism in all the paralysed muscles, but the muscles of the hand responded normally. The child bore a very strong current without evincing any signs of pain. In short, the child had an almost complete flaccid paralysis of all the muscles of the neck, trunk, and limbs, the muscles of the face, eyes, and diaphragm alone remaining normal.

Dr. WILFRED HARRIS considered that Dr. Batten had proved his case, and Dr. POYNTON related some cases in which the arms were completely paralysed; the fingers and toes, however, were just able to be moved.

## SECTION OF ANÆSTHETICS.

*Death under Chloroform.—Anæsthesia in Post-pharyngeal Abscess.—Reflex Effects from Stimulation of the Nasal Mucous Membrane during Anæsthesia.—Cheyne-Stokes Respiration during Anæsthesia.*

A MEETING of this section was held on Feb. 3rd, Dr. W. J. MCCARDIE, the President, being in the chair.

The PRESIDENT reported a case of Death under Chloroform due to inspiration of gummatous material. The patient, a man aged 43 years, was to be operated on for ulcer of the scrotum and hernia of the testis. The house surgeon administered chloroform on a Schimmelbusch mask, this anæsthetic being selected on account of the presence of bronchitis. There was slight struggling during induction. When the patient

was moved on to the operating table severe cyanosis and embarrassed respiration suddenly occurred, respiration shortly stopping entirely. The pulse was good when the respiratory failure occurred. Restorative measures were of no avail. Post mortem, a broken-down gumma was found at the bifurcation of the trachea, which had evidently burst during the anæsthesia.—Dr. BARTON questioned whether in view of the existing bronchitis the case should have been operated on at all.—Mr. C. CARTER BRAINE asked whether artificial respiration had been performed with the patient lying on his side.

Mr. R. GILL read a short paper on Anæsthesia in Post-pharyngeal Abscess. He described a case of a child, aged 3 months, with difficulty in breathing, who was to be operated on for adenoids. Light anæsthesia was induced with chloroform. On opening the mouth a swelling was seen bulging forward from the back of the pharynx which produced further obstruction the more the mouth was opened. The mass was incised and a large quantity of matter rapidly discharged, filling mouth and nose. The child, who had become dusky, was suspended head downwards. After the matter had been rapidly swabbed out, the tongue was hooked forward by passing the finger along the dorsum. The patient recovered. Great stress was laid on the importance in this case of the inverted position. Mr. Gill also reported a case in which during an operation on the chest there was sudden hæmorrhage from the nose and mouth, producing symptoms of suffocation. The patient's head was lowered over the end of the operating table, and when the flow of blood had diminished the anæsthetist drew the base of the tongue forward with his finger, compressing meanwhile the chest with his elbows.—Mr. H. BELLAMY GARDNER considered that it would be better to operate on cases of post-pharyngeal abscess without an anæsthetic. The operation was generally trivial.

Dr. J. BLUMFELD read a short paper on Reflex Effects from Stimulation of the Nasal Mucous Membrane during Anæsthesia. He described a case of heart failure after the injection of adrenalin. The patient who was to be operated on for deviated septum was anæsthetised with C E. mixture. In seven minutes he was declared ready, the colour was good, and corneal reflex present. He was placed in a sitting posture and as there was slight coughing more anæsthetic was administered. Six minims of a 1 in 4000 solution of adrenalin were then injected into the nasal mucous membrane. Immediately there was extreme pallor, dilated pupil, and the usual symptoms of severe cardiac depression. These passed off and the operation was performed without further trouble, chloroform being administered by Junker's apparatus.—Dr. A. L. FLEMMING had seen faintness caused by adrenalin, but not by weak solutions; he considered 1 in 4000 too strong.—Mr. BRAINE recorded a case in which sudden death had followed the injection of adrenalin into the tonsil in the case of a girl who was to undergo tonsillotomy.—Dr. R. J. PROBYN-WILLIAMS questioned whether the change to the sitting posture might not have been a factor in the depression produced.—Dr. J. F. W. SILK thought that the drug was the chief cause; he had seen faintness produced by plugs of cocaine and eucaine in the nose.—Mr. BELLAMY GARDNER believed that adrenalin injected into the tissues caused shock, but when it was *applied* only it did not do so. He did not believe in the sitting posture as a causal factor.—Mr. H. S. BARWELL said that he was the operator in the case described by Dr. Blumfeld. The shock did not appear till some time after the sitting posture had been assumed, and he considered that it was due to the adrenalin. He found that adrenalin had a much more depressing effect on anæsthetised than on conscious persons, and for the latter he often used large doses with impunity. He had never seen a case of shock under adrenalin when the anæsthesia was induced by ether.—Dr. F. W. HEWITT considered that the low blood pressure under chloroform was an important factor in the circulatory depression produced by adrenalin, and explained why it was that such depression did not occur in etherised or conscious patients.—The PRESIDENT stated that he also had had cases of circulatory depression due to adrenalin. He advised interruption of the administration of the anæsthetic for a time during the injection of adrenalin.—Mr. HARVEY HILLIARD stated that he had seen cases of cardiac inhibition when plugging the nostrils under anæsthesia, but not when the plugging was performed previous to induction.

Dr. C. H. M. HUGHES made a short communication on Cheyne-Stokes Respiration during Anæsthesia. He described the case of a man, aged 52 years, who underwent gastrostomy for malignant disease of the larynx after tracheotomy. Chloroform was administered on lint over the tracheotomy opening and followed by C.E. After about four minutes respiration stopped, the pupils being small, and corneal reflex present. After 30 seconds breathing was resumed. Throughout the operation, which lasted about 45 minutes, there occurred about every five to ten minutes periods of apnœa of 30 to 40 seconds, alternating with regular breathing of good volume. There was no straining. After the anæsthesia was stopped the condition gradually passed off.—Dr. BARTON had seen at least half a dozen cases of Cheyne-Stokes breathing under anæsthesia. They were all either under chloroform or C.E.—The PRESIDENT had found six cases in his records; they were all but one old men with rigid chests. The one exception was a man aged 48 years, who was operated on for cerebral tumour under chloroform and C.E.

Mr. F. COLEMAN showed a new form of Stopcock for Gas and Air Administration.

## LARYNGOLOGICAL SECTION.

*Exhibition of Cases and Specimens.*

A MEETING of this section was held on Feb. 3rd, Dr. P. WATSON-WILLIAMS, the President, being in the chair.

The following cases and specimens were shown:—

Dr. G. WILLIAM HILL, in conjunction with Dr. G. HERSCHELL, demonstrated on the living subject a combined direct and indirect method of Œsophago-gastroscopy. An excellent view was obtained of the stomach and lower part of the œsophagus, and the great value of this method was pointed out. The stomach was dilated with air and previously washed out by a special instrument.

Mr. FRANK A. ROSE and Mr. CECIL I. GRAHAM: Cases of Tuberculous Tonsillitis, this in Mr. Graham's case being associated with tuberculous laryngitis. An interesting discussion resulted with reference to the frequency of primary tuberculous disease of the tonsils.

Mr. HERBERT TILLEY: Plaster casts of an Unusual Malformation of the Upper Jaw. There was a markedly V-shaped condition of the hard palate, while the alveolar borders of the upper jaw were hypertrophied. There were also well-marked alar collapse and much septal irregularity. Pyorrhœa alveolaris was also present.

Dr. L. H. PEGLER: Cases of Malignant Disease of the Larynx and extensive Ulceration of the Pharynx and Tonsils, considered malignant. Also a case of Tuberculous Disease of the Vocal Cords, with secondary tuberculous infection of an adenoid growth in the naso-pharynx. The patient was a fur sorter. Both cords were thin and ulcerated; the right cord was also longitudinally split. They approximated badly, causing complete aphonia, but there was neither pallor nor œdema. There were no lung signs, sweating, or loss of flesh. The general health was excellent. Since the first onset a small mass of adenoids had become ulcerated. Sections of this under the microscope displayed giant cell systems, and though staining of tubercle bacilli had not been successful, matter obtained thence and injected into guinea-pigs infected the glands and viscera. A preparation from one animal was shown, and a section of one of the guinea-pig's glands showing tubercle bacilli. Von Pirquet's reaction was negative in this patient.

Mr. E. A. PETERS: Malignant Disease of a Tonsil, with enlarged glands in the neck, now undergoing treatment by radium.

Dr. J. DONELAN: Swelling at the Junction of the Right Vocal Cord and Apex of the Vocal Process in a professional singer aged 52 years.

Dr. DAN MCKENZIE: Papilloma of the Larynx in a child. Obstruction to breathing had been so great that tracheotomy had to be performed six months ago; subsequently several papillomata were removed by the direct method.

Mr. G. W. BADGEROW: A case of Lingual Thyroid in a female aged 17 years. There was a hemispherical swelling over the base of the tongue, which was hard to the feel.—Mr. H BETHAM ROBINSON detected enlarged glands in the neck, and thought the case might possibly turn out to be one of lymphoma or lympho-sarcoma.

Dr. G. C. CATHCART: A case of Aphonia (recurrent) in a woman aged 36 years. The patient had been in the Mount

Vernon Hospital. On laryngological examination it was seen that the mucous membrane over the arytenoids and inter-arytenoid space was swollen and that the cords did not meet properly.—Dr. W. JOBSON HORNE pointed out the probability of certain cases of aphonia supposed to be hysterical being really tuberculous.

Mr. SOMERVILLE HASTINGS: A case of Ulceration of the Left Tonsil in a man aged 56 years. The ulcer had lasted for over two months with very little alteration. It extended to the anterior pillar of the fauces, and presented a curious dead-white appearance. There was no history of syphilis, but pyorrhœa alveolaris was present. Klebs-Löffler bacilli could not be found, and the microscopical appearances of a piece removed did not favour malignancy. No glands could be felt.—Dr. W. H. KELSON pointed out how much the dead-white appearance resembled that seen in certain malignant growths of the larynx.

Mr. NORMAN PATTERSON: 1. Primary Sore in the Vestibule of the Nose in a female patient aged 38 years. The lesion was an indurated area which gradually increased in size, and was accompanied by some enlargement of the glands in the submaxillary region. There had been a great deal of pain, extending on to the face. Spirochætæ had been found and a positive Wassermann reaction obtained. 2. Epithelioma of the Epiglottis in a man aged 40 years. The patient had noticed pain on swallowing for the last two months, and shooting from the tip of the great cornu of the hyoid bone on the left side towards the back of the ear. He complained of a great tendency for the saliva to accumulate in the throat. Some glands were felt, especially on the left side, which might perhaps be accounted for by the septic condition of the teeth.

The PRESIDENT: A man suffering from Stricture of the Œsophagus situated 11½ inches from the incisor teeth. It was considered to be malignant, and was shown to elicit views as to the suitability of treatment by radium or otherwise.

Dr. H. W. FITZGERALD POWELL: A man, aged 48 years, with history of difficulty in breathing of six months' duration. Examination showed a large mass of growth involving the left side of the larynx, filling up the cavity of that organ, involving the tongue and aryepiglottic folds. There was a history of syphilis, but the Wassermann reaction was negative.

Dr. H. J. DAVIS: A man, aged 71 years, whose upper jaw had been excised for Malignant Disease of the Antrum, following polypi and antral empyema. Some œdema of the lower eyelid still remained.

Dr. HILL: Tuberculous Disease of the Nose in a child. There had also been disease in the superior maxillary bone on the left side.

## OPHTHALMOLOGICAL SOCIETY.

*Histo-pathology of Papillœdema.—Exhibition of Cases.*

A MEETING of this society was held on Feb. 9th, Mr. GUSTAVUS HARTRIDGE, Vice-President, being in the chair.

Mr. LESLIE J. PATON and Dr. GORDON M. HOLMES communicated a paper on Histo-pathology of Papillœdema. It was a preliminary account of their investigations into the pathology of papillœdema. Their work was based on the histological examination of 60 eyes, all from cases in the National Hospital for the Paralysed and Epileptic, Queen-square, Bloomsbury. The conclusions they formed from these cases were that the so-called "optic neuritis" was a simple congestive œdema of the disc, and was not in any way an inflammatory phenomenon. Inflammation when it did occur was slight in amount, limited in its distribution and secondary in its nature. The hæmorrhages that occurred were in the main congestive, but partly due to stretching and rupture of small vessels by the swelling disc. The larger white patches that occurred on or near the disc were due to degeneration of the nerve fibres. This degeneration showed itself first by varicosities appearing on the nerve fibres, which later swelled up into elliptical or globular bodies known as "cytoid bodies." These might lose their connexion with the nerve fibre from which they developed, and consequently undergo fatty degeneration. The smaller bright-white spots arranged in fan-shaped fashion between the disc and macula were due to œdema raising the membrana limitans interna into vesicles. The changes produced as the disc became atrophic were, (*a*) occlusion of the smaller vessels by endothelial proliferation and adventitial thickening in the walls of the larger vessels; (*b*) a glial proliferation which varied in intensity with the degree of atrophy; and (*c*) proliferation in the mesoblastic tissues round the blood-vessels and without, forming the lamina cribrosa. Mr. Paton and Dr. Holmes considered that the hypothesis which best explained all the known facts of tumour papillœdema was that, owing to the rise of intracranial pressure, there was a communicated rise of pressure in the nerve sheath. The portion of the central vein lying in the nerve sheath behaved, in response to this raised pressure, like a cerebral vein, and the blood pressure in it was consequently raised to the same extent. This produced a congestion of all the connexions of the central vein distal from that point. In addition to causing venous congestion the raised intra-vaginal tension obstructed the normal drainage of lymph from the disc and nerve and caused a lymph stasis, so that there was both an increased output and a diminished drainage. The tissue tension in the nerve itself was raised, so there was no marked difference between intravenous pressure and tissue pressure until the lamina cribrosa was reached within the range of the relatively lower, though normal, intra-ocular tension. The paper was illustrated by a number of lantern slides.—Mr. S. JOHNSON TAYLOR asked whether Mr. Paton and Dr. Holmes had seen any case early enough to confirm what was clinically found—viz., that the earliest evidence of optic neuritis was in the upper and inner part of the disc. He had under his care at present a case which confirmed that.—Dr. JAMES TAYLOR spoke appreciatively of the extensive nature of the research. It occurred to him that it might lead to a revival of the old method of tapping the optic nerve from the front with the view of relieving the œdema. If so, that would cause one to view more hopefully cases of extreme papillœdema.—Dr. HOLMES, in reply to Dr. Taylor, said the method mentioned would only be feasible if a fistula were left in the sheath to allow the cerebro-spinal fluid to drain away.—Mr. PATON replied that the papillœdema nearly always commenced at the upper border first and later in the lower. But when only the upper border showed œdema there was shrinkage of the tissue. The disc looked normal, but there was evidence of slight œdema commencing at its upper edge.

Mr. E. W. BREWERTON showed a case of Symmetrical Marginal Corneal Degeneration.

Mr. H. B. GRIMSDALE showed a patient with Irideremia and Deformity of Lens.

Mr. C. HIGGENS showed a patient on whom he performed his operation of Dacryocysto-rhinostomy, and described the procedure.

Mr. E. TREACHER COLLINS exhibited a case of Widespread Exudation internal to the choroid and beneath the retinal vessels, giving rise to a white reflex.

## SOCIETY OF MEDICAL OFFICERS OF HEALTH.

*The Sanitary Service of the Territorial Force.*

A MEETING of this society was held on Feb. 10th, Dr. W. G. WILLOUGHBY, the President, being in the chair.

Lieutenant-Colonel C. H. MELVILLE, R.A.M.C., professor of hygiene, Royal Army Medical College, London, introduced a discussion on the Sanitary Service of the Territorial Force. He dealt mainly with the duties of those officers of the Territorial sanitary service whose services would be available on mobilisation, or as they are sometimes termed, officers on the *à la suite* list, of whom 106 had been gazetted. He touched briefly, however, on some of the duties of the divisional sanitary officer, which were very extensive and brought him into connexion with the life of the soldier at all points, except those connected with actual fighting. Thus he had to exercise a general supervision over the sanitary condition of all places occupied by the troops of the command to which he was attached, watch the health conditions of all camps, &c., and investigate the cause of any undue prevalence of disease among the troops or the inhabitants. He had to advise on the selection from a sanitary point of view of sites for camps

and bivouacs, and on questions relating to the sanitary conditions of towns, villages, or buildings about to be occupied. He must advise regarding the purification and distribution of water for drinking purposes, with respect to latrines and urinals, the disposal of refuse, the burial of the dead, and the disposal of the carcasses of animals. The duties of *à la suite* officers referred to the habitations of troops whether in camps or in buildings, to water-supplies, to roads, to the prevalence of infectious diseases in various localities, and such-like matters. The quartermaster-general's department would require advice as to the suitability from a sanitary point of view of buildings to be used as temporary barracks and of camping grounds. The information required of the sanitary officers was given in some detail by Colonel Melville, who then referred to the necessity for describing the water-supply of a district as a whole. For this purpose each stream or river should be traced from its source, till it passed into some other district. The presence of any dangerous source of pollution should be noted, with its exact position and distance from the water. This collection of information would fill a very serious gap in our knowledge, and any officer on the *à la suite* list who should set about collecting it as regards his own district, and more especially along the main lines of communication, would be doing a useful piece of work and rendering the State good service. Other duties of the sanitary officers would include the cleaning up of camping grounds after they had been utilised by troops passing hurriedly through a district, and maybe the cleaning up of a battle-field. Colonel Melville emphasised the necessity of every sanitary officer at once making himself familiar with his duties and at once setting about the collection of information which would be available when the emergency arose. Every officer, he said, who promised that his services would be available on mobilisation was bound by every rule to see that his services were worth having on mobilisation.

In the course of the discussion the PRESIDENT pointed out that Colonel Melville's paper was not by any means confined in interest to the officers in the *à la suite* service, but that it concerned all medical officers of health.

Mr. F. E. FREMANTLE considered that the scheme of duties presented was not at all complete. In the event of a war in this country the Territorial Forces would have to depend, so far as sanitation was concerned, upon the civil sanitary administration, and this should be brought into closer touch with the military sanitary service.

Mr. E. SERGEANT and Dr. J. R. KAYE emphasised the importance of a foreknowledge of suitable camping grounds and of water-supplies. Dr. Kaye also pointed out that the art of hygiene was as important in warfare as the art of strategy, and that disease was the master in every campaign.

Dr. P. CALDWELL SMITH referred to the desirability of the members of the *à la suite* service obtaining a knowledge of camp life and of military sanitation.

Mr. H. BEALE COLLINS and Mr. HERBERT JONES considered that the whole country should be mapped out into areas which should be allotted to particular members of the service.

Professor W. R. SMITH agreed that it was of the greatest importance for the *à la suite* officers to become familiar with military life, and that they look at their work through military spectacles.

Dr. W. BUTLER, Dr. H. COOPER PATTIN, and Mr. J. TUBB-THOMAS also took part in the discussion.

## EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

*Acute Anterior Poliomyelitis.—The Medical Examination of Employees.—Exhibition of Cases.*

A MEETING of this society was held on Feb. 1st, Dr. BYROM BRAMWELL, the President, being in the chair.

Dr. EDWIN BRAMWELL and Dr. D. W. CURRIE read a paper on Acute Anterior Poliomyelitis. No disease had occupied such a prominent place in neurological literature during the past year or two. Epidemics had occurred in many parts of Europe and America during the last hemi-decade. A localised epidemic was described. The character of the symptoms was instructive. The epidemic consisted of five cases. Five of 12 children living in a farmstead which consisted of four dwelling-houses were affected. Three of four children in one house suffered and both children in the adjacent house. Fever, headache, pain at the back of the neck, neck rigidity, and head retraction were conspicuous features. Vomiting occurred in two cases. In one of the first cases pain in the lower limbs was so severe as to suggest acute rheumatism. All the patients recovered. Two presented paralysis of the limbs with abolition of the tendon jerks and other features characteristic of typical poliomyelitis. In one case a temporary facial paralysis and in another a strabismus were the only paralytic symptoms. The fifth patient recovered without manifesting definite paralysis at any period. The circumstance that the five patients were taken ill within a few days of one another (Sept. 12th to 24th), together with the similar symptoms of onset, makes it certain that all the cases were due to the same causal agent. Three of the cases might well have escaped recognition had they been met with singly. The number of cases with cerebral palsies and in which complete recovery had taken place had been a generally recognised feature in recent epidemics. This epidemic was extremely instructive in relation to the incubation period of the disease. The farmstead in which the patients lived occupied a somewhat isolated situation, and the individual cases developed one after the other. The two families might be conveniently designated A and B and the children Aa, Ab, Ba, Bb, Bc, and Bd. Ba, Bb, and Bc slept in the same bed, while Bd slept in a cradle in another room together with Mr. and Mrs. B. Bb first manifested symptoms on Sept. 12th, Ba on Sept. 16th, and Bd on Sept. 18th, while Bc escaped. Ba was no doubt infected by Bb. Bd might have been infected either by Bb or Ba, or the infection might conceivably have been carried by Mrs. or Mr. B. In this connexion it was interesting to note that on and after Sept. 14th Bb slept in the same room as Bd. Ab was taken ill on Sept. 20th, Aa on Sept. 24th. Aa was no doubt infected by Ab, for they slept in the same bed. It would seem almost certain that Ab must have been infected by one of the B's. Both Mrs. A and Mrs. B positively stated that the A children had not been in the B's house, or the B's in the A's house after Bb was taken ill. On Sept. 16th, and again on the 18th and 19th, Mrs. A visited the B's, and on each of the two dates last mentioned she remained in the house for several hours helping to nurse Bd. These data would seem to indicate that the incubation period in this particular epidemic was four days, or not longer than four days, while they suggest that the infection might be carried by a third person. The comparative frequency of poliomyelitis during the past autumn was next referred to. Statistics for several years from the Edinburgh Royal Hospital for Sick Children and other hospitals were presented, and numerous opinions quoted from different centres in England and Scotland in order to demonstrate the truth of this assertion. It was further mentioned that two or three local epidemics had occurred recently in various parts of England. So far as Dr. Bramwell and Dr. Currie could ascertain no abnormal increase in frequency of the disease, curiously enough, had been observed in London. Finally, the possibility of some sort of relationship between poliomyelitis and epidemic cerebro-spinal meningitis was referred to. Dr. Bramwell and Dr. Currie would have it clearly understood that they fully realised the existence of certain pronounced points of difference, yet they were of opinion that the possibility of some association between the two diseases was worthy of consideration. Both diseases occurred in a sporadic and epidemic form, both affected children more especially, in both the degree of contagion appeared to be much the same, and in both the initial symptoms were very similar. The most striking point, however, was the circumstance that a few years ago epidemics of cerebro-spinal meningitis, previously of great rarity, were met with in many localities throughout Europe and America, while two or three years later epidemics of poliomyelitis, practically unknown hitherto, were of widespread occurrence.

—Dr. G. H. MELVILLE DUNLOP said that he fully endorsed the fact that recently there had been a severe and widespread epidemic of poliomyelitis in the country, and his own experience had borne this out. Within the last six months over 40 cases had been under treatment in the Royal Hospital for Sick Children. The average usual number in his own

ward was one or two, as contrasted with 16 at present, and he had noted the same increase in private practice. He had remarked on the very severe and prolonged character of the premonitory symptoms and on the difficulty, or even impossibility, of arriving at an early diagnosis, as, for example, the child lying comatose for ten days before paralysis showed itself; in other cases there was wild delirium preceded by convulsions, while in still others the symptoms were those of tuberculous meningitis. He referred to the widespread nature of the paralysis in many cases and to others in which bulbar symptoms were present. In two cases he had observed paralysis of the face as well as paralysis of the limbs. From 70 to 80 per cent. of the cases occurred within the first three years of life, but he had been struck with the fact that in the present epidemic the average age was much higher—viz., from 4 to 11 years. The prognosis was, however, very much more satisfactory than what one had been accustomed to give formerly, and he had noted complete recovery taking place within four months even in cases of complete paralysis. In the great majority of cases the prognosis was entirely favourable.—Dr. J. H. HARVEY PIRIE said that he had seen the cases described along with Dr. Currie. Some were very interesting as diagnosis could not have been made unless for the epidemic nature. If cases should recur this summer special attention should be paid to early diagnosis with a view to early isolation. The disease began as a meningitis and this accounted for the headache, rigidity, and fever as early symptoms. An examination of the cerebro-spinal fluid was useful in the prodromal period as it showed increased pressure and excess of mononuclear cells, which signs disappeared when paralysis came on. He thought that the use of urotropine was beneficial in such cases as formalin was rendered free in the cerebro-spinal fluid.—The PRESIDENT alluded to the fact that the symptoms in the epidemic form of the disease differed from those observed in sporadic cases. In the epidemic under discussion the cases were so isolated that they allowed conclusions to be drawn very clearly. Fixing the incubation period at or about four days seemed an important point. It was unfortunate that bacteriology afforded no help in the diagnosis of poliomyelitis while it revealed the organism in cerebro-spinal meningitis.—Dr. A. DINGWALL FORDYCE, Dr. JOHN THOMSON, and Dr. W. T. RITCHIE took part in the discussion.

Dr. H. G. LANGWILL read a paper on the Medical Examination of Employees. He said that the practice of making a medical inspection of individuals with a view to the early detection of actual disease or a liability thereto was becoming of recent years more widespread. The need for a wider inspection of workmen in all kinds of employment had been borne in upon employers in view of the recent Workmen's Compensation Acts, and more especially the wide interpretations which had been given in various courts to the term "accident." It was not to be wondered at that shipowners had found it still more urgently necessary for their employees to be medically examined because of (1) the essentially hazardous nature of much of their work; (2) the shipowner was liable for accidents not only when their employees were at their work but also when they were asleep (thus, if a seaman were injured while in his bunk (e.g., by a collision) he fell to be compensated, the work being a "whole-time" employment); (3) owing to the absence in the great majority of seagoing vessels of any qualified medical aid a slight injury might have serious or fatal results; and (4) under a recent Merchant Shipping Act the owners were liable for the expense of treatment of illness in any member of the crew, and if he had been left ashore for treatment they were liable for his expenses until he was landed in the United Kingdom. The detection of any probable causes of disability before the man joined his ship was of considerable importance. No substitute for a sick man could be got at sea, and the vessel had to be worked by those who were fit. This system of inspection was instituted in 1907 by the Shipping Federation, who under the guidance of skilled medical men drew up a uniform system of medical examination for use in all ports, a method of recording the results and a schedule of the various diseases or surgical affections to be reported on. Dr. Langwill held strongly that there was not the same need for a high standard of physical fitness in the case of men making short voyages as contrasted with those taking voyages of weeks' or months' duration. Medical examiners were appointed for each port and their duties were: (1) to medically inspect each member of the crew before "signing on"; and (2) to examine employees who alleged that they had sustained injuries at their work. Dr. Langwill emphasised that it was only an *inspection* or survey of the men that was made and not a medical examination of a patient in the ordinary sense. It was thus different from the medical examination of entrants to the Post-office, Customs, &c.—no family history was asked nor was the urine examined. The main points to which attention was directed were: (1) Eyesight; (2) hernia; (3) venereal diseases; (4) varicose veins; (5) ulcers or previous injuries; (6) heart and blood-vessels; and (7) giddiness and fits. The original instructions stated that "only officers and deck hands were to be tested for form and colour tests"; firemen and stewards were exempted, but defective eyesight in any employee on board ship might result in serious financial consequences for the owner owing to permanent blindness resulting from slight injury or disease in a patient unable to secure skilled treatment at the proper time. Thus from a compensation point of view a good standard of eyesight was necessary. Dr. Langwill had found it very difficult to test firemen by the ordinary types, as owing to the glare of the furnaces they cannot see letters clearly at a distance. Personally, he was inclined to advise the rejection of a fireman who had practically only one eye available for distant vision, as the risk of accident to this eye had always to be borne in mind. As regarded officers and deck hands, the Board of Trade did not at present require the eyes to be tested separately, and the standard at present required was that more than half the letters in the fifth line of the test Snellen's sheets must be read correctly at 16 feet. Unless there was apparent inequality of visual power in the two eyes he did not test the eyes separately. Fairly frequently it occurred that the seaman who was very defective in making out the test-types was yet said by his officers "to be very good at picking up the land or lights at sea." Dr. Langwill supposed that the man's *light sense* was better than his *form vision*, and that it was the *light sense* which was relied upon greatly in "look-out" duty. In testing *colour vision* wools were used, but instead of asking the candidate to match certain colours Dr. Langwill's practice was to show him a red or green skein, and on his naming it correctly to ask him to pick out some more reds or greens while the examiner concealed the original skein. What was required of the seaman was to pick up a red or a green light *individually* at sea and not by comparison. Coloured lights took on different tints in foggy or misty atmospheres, and the most practical method of testing colour vision would be to try the man at sea with actual lights under various weather conditions. A large proportion of Dr. Langwill's defective colour candidates came from Orkney and Shetland. Hernia occasioned the rejection of a goodly proportion of men. When the hernia was small and kept up by a well-fitting truss the man was usually passed, but Dr. Langwill had doubts as to the advisability of this, as the truss was not always worn and was not always effective in severe straining or might be broken. He asked if a man who had had a "radical cure" performed was really no more likely to develop hernia again than one who had never been ruptured. He felt inclined to order a man who had been radically cured at least to possess a truss for use if bulging should show itself. Was the risk of strangulation as great in the case of old-standing hernias as in those newly developed? Should a man with a small umbilical hernia be rejected? Did strangulation occur at all often in the hernial protrusions at abdominal scars? Venereal diseases did not bulk so largely as might have been expected. Out of 930 men examined in 1910 only seven were rejected from this cause. It was difficult to know how to act as regarded varicose veins. Unless they were very pronounced the man was generally passed on condition that he wore an elastic stocking. Heart and blood-vessels:—As regarded valvular disease, if compensation was well established the man was usually passed. Unless the voyage was long, when he was advised to seek another ship, aneurysm formed one of the most difficult problems, and especially after the recent decision of the House of Lords, and the detection of intra-thoracic aneurysm was very difficult. As to the fitness of an employee to resume work after an illness, that was not always easy to answer. Of two men sent to him suffering from "cardiac debility" he found that one had suffered from recurring attacks of dyspnœa and debility for 15 years, while the other gave a

history of marked anginal attacks of recent date after exertion and having a very high tension pulse. Dr. Langwill advised the employers as regarded the latter man that they ran undoubted risk from his death occurring suddenly. As regarded examination of employees *after injuries* last year he reported on upward of 60 such cases. A very real difficulty was that of getting *after-treatment* of the patient carried out after the man had ceased attending hospital; thus joints might become permanently stiff and the prospect of resuming work was remote in such circumstances. Until the law allowed part of the compensation benefits to be expended by the employer in getting the man fitted for his work, the only way seemed to be to keep the man under treatment by the house surgeon. Another trouble was that the health of the man might suffer as a result of the endeavour to live on half pay compensation money. A third difficulty was that of starting seamen after an injury with any kind of light work and unless he were "able-bodied" he might be a source of compensation risk to the employers.—Professor F. M. CAIRD thought that in every case of hernia in seafaring men a radical cure should be performed, as in the majority of cases a perfectly good result was obtained, and in those candidates for the army and navy upon whom he had operated there had been no relapse. Still, each man so treated should possess a truss in case of accidents. He thought that the older-standing hernias with a large ring were less likely to become strangulated than those with a small opening.—Dr. D. CHALMERS WATSON, Dr. W. MACRAE TAYLOR, Dr. JAMES RITCHIE, Mr. ALEXANDER MILES, and the PRESIDENT took part in the discussion.

Professor CAIRD showed (1) Carcinoma of the Rectum removed by the abdomino-sacral method. The patient was a woman, aged 57 years, who had had symptoms of rectal carcinoma for four months. Local examination revealed a large tumour encircling the bowel just within reach of the finger. An operation was performed on Dec. 20th, 1910. The abdomen was explored and the tumour found at the floor of the pouch of Douglas; the peritoneum round it was divided. A parasacral incision was made and the lower end of the sacrum divided; delivery of the tumour was accomplished through the sacral wound; it was resected, and end-to-end suture of the bowel was performed.

Professor H. ALEXIS THOMSON showed a boy, aged 13 years, who had been run over by a motor-car on Oct. 27th, 1910, and admitted to the hospital unconscious. Blood was present in the vomit and in the urine. An apparently complete recovery took place. He was, however, readmitted on Nov. 29th on account of sickness and with a swollen, tense abdomen due to an accumulation in the lesser sac. On the following day the abdomen was slack, the fluid having escaped into the greater sac. Incision and drainage of both sacs was performed, the fluid in the sacs being quite clear. He was discharged, but again readmitted on Jan. 20th, 1911, with another tense accumulation in the lesser sac. Formerly such cases were termed pancreatic cysts; they were probably traumatic effusions due to a tearing of the peritoneum.

## GLASGOW OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

*Pathology of the Embryo in Relation to Abortion.—Congenital Stenosis of the Pylorus in an Infant.—Exhibition of Specimens.*

A MEETING of this society was held on Jan. 25th, Dr. A. W. RUSSELL, the President, being in the chair.

Dr. JOHN LINDSAY read a paper on the Pathology of the Embryo in Relation to Abortion. He showed photomicrographs of five embryos of the first and second months, all of them malformed and four of them dwarfed. There was demonstrated from the sections cell proliferation in the mesoderm such that the tissue did not grow, but its meshes became filled with small round cells which also invaded the hollow organs and body cavities, the specialised tissue cells disappearing before the invasion. The whole of some of the embryos and parts of others showed only undifferentiated round cells in various stages of degeneration. The evidence was clear that the degenerative changes were necrobiotic and not due to post-mortem maceration. The ectoderm was intact and well preserved in all the embryos. The pathology being that of malnutrition, the causation was referred to maternal blood states, and it was suggested that similar changes leading to the dissolution of minute embryos rather than the maceration of embryos of a size conforming to the gestation period accounted for the empty decidual sacs which were frequent in abortions of the second month.—Dr. A. LOUISE MCILROY asked if there was evidence of thyroid insufficiency in any of the maternal cases. The statement that albumin in the urine was associated with malnutrition in the embryo was of interest when it was remembered that experimental work on cats showed that removal of the thyroid caused albumin in the urine, and the removal of the thyroid in pregnant animals caused hypertrophy of that gland in the fœtus with diminished function.—Dr. J. H. TEACHER agreed with the conclusions that erroneous development of the embryo was a common cause of abortion, and that it was in all probability the expression of defective nutrition or toxic influence acting through the medium of the maternal blood. With regard to those cases in which the embryo was entirely absent, he was of the opinion that they were more readily explained by complete failure of development on the part of the embryonic rudiment than by maceration of an embryo which had been formed and possibly grown to a considerable size. While the latter cause could not be excluded, it was apparent from the condition found in the very earliest stages that the embryonic rudiment might be completely absent—e g., Leopold's ovum of 1·5 millimetres. While it was probable that ova of this class would be extruded at a very early stage, it was clear that there was sufficient power of independent growth in the placental portion of the ovum to permit of development to a considerable size. In cases of this class there might be not so much unsatisfactory nutritive conditions as simple lack of formative power in the fertilised ovum, so that although the early stages of formation were passed in safety, a time came when the power of growth was spent and the ovum ceased to grow and was expelled. He disagreed with Dr. Lindsay as to the greater frequency of abortion in ova fertilised towards the end of the intermenstrual period. Doubtless on the analogy between the œstrous cycle and the menstrual cycle, the earlier part of the period might reasonably be regarded as the normal one for fertilisation, but facts were wanting to prove that the latter part of the period was unfavourable to continued development, and the histories of various ova which had been admitted to the Normen-Tafeln of Human Embryology (Keibel) showed that normal development might result from fertilisation in the latter parts of the intermenstrual period.

Dr. J. T. WEST read a paper on, and showed specimen of, Congenital Stenosis of the Pylorus in an Infant. The child was quite healthy at birth, and weighed 7½ pounds. It was applied to the breast on the second day and suckled at regular intervals. When it was one month old vomiting began and gradually became much worse. The child lost weight. The abdomen was distended on account of the dilated stomach and the characteristic splashing sound could be easily elicited on shaking the child. On deep palpation in the pyloric area a fusiform mass could be felt. Medical treatment having had no effect the question of operation was raised, but the parents would not give their consent. Twenty-four days after the onset of vomiting the child died in a comatose state. At the necropsy the small and large intestines were found empty; the stomach was large, its walls thickened, and its capacity was found to be 4½ ounces. At the pyloric end there was a large mass of cartilaginous firmness. The stomach and duodenum were empty.

The PRESIDENT showed a specimen of Congenital Stenosis of the Pylorus in an infant.

Dr. DAVID SHANNON showed: 1. A Large Fibroid of the Uterus which had undergone cystic degeneration. It weighed nearly 14 pounds. 2. A well-marked case of Chorio-epithelioma. 3. A Small Uterus with numerous Interstitial Fibroids and one Submucous. Myomectomy had been performed in this case nine years ago.

MEDICAL SOCIETY OF LIVERPOOL.—A pathological meeting of this society was held on Feb. 2nd, Dr. T. R. Bradshaw, the President, being in the chair.—Mr. K. W. Monsarrat exhibited specimens of Adenoma of the Palate, Colloid Carcinoma of the Cæcum, Carcinoma of the Bladder, Fibro-chondroma of the Submaxillary Gland,

Resected Intestine and Sac from Strangulated Umbilical Hernia.—Mr. Douglas Crawford and Dr. D. Moore Alexander showed specimens of: 1. Primary Tubercle of the Tongue from a patient aged 27; the ulcer was situated near the tip of the tongue. Anti-syphilitic treatment had been tried before excision, but with no result. 2. Secondary Tubercle of the Tongue in a man aged 45. The ulcer was situated on the side of the tongue opposite the second molar tooth; there was slight evidence of tubercle at the apex of the right lung. Tubercle bacilli were found microscopically in this specimen, but not in the first. 3. Sarcoma of the Thyroid from a woman aged 50. The tumour had been there for some years, and had grown rapidly in the last six weeks. 4. Acinous Cancer of the Hard Palate in a patient aged 65.—Mr. G. P. Newbolt showed specimens of Appendix and Liver Abscess and of Richter's hernia.—Dr. Alexander showed a culture of Bacillus Lepræ.—Mr. Arthur J. Evans showed Chondro-sarcoma of the Testicle.—Mr. Frank Jeans showed: 1. A Fallopian Tube containing a very early ectopic pregnancy—presumably about 14 days. The symptoms simulated acute intestinal obstruction. 2. A Calculus removed from the ischio-rectal fossa of unknown origin, possibly from the urinary bladder or from the biliary passages. 3. An Intussusception which he had removed from a woman, aged 21 years, involving 3 or 4 feet of jejunum, about 6 inches below the duodenum.—Mr. W. Thelwall Thomas and Dr. G. Stopford Taylor showed a Sacrococcygeal Dermoid from a woman aged 26 years; large cysts lined by squamous epithelium existed in both buttocks; in the post-rectal region the growth was sarcomatous.—Mr. R. E. Kelly and Dr. Ernest Glynn showed a Glioma from the right lobe of the cerebellum from a girl aged 3 years, in which there was a cyst which had been successfully drained three months before death with relief of all symptoms; also a typical Squamous-celled Epithelioma from the substance of the interior of the breast which had probably originated in a dermoid.—Mr. F. T. Paul showed a Fibro-cystic Tumour of the Testicle and an Adeno-chondroma of the Pharynx, and a Perithelioma of the Breast.—The President and Dr. Glynn showed a Chronic Ulcer of the Stomach which caused profound anæmia from concealed hæmorrhage; at one end of it colloid cancer was commencing.—Dr. Alexander related three cases of infection by the Bacillus Aerogenes Capsulatus. Two of these presented the commoner features of infection through wounds, both being cases of accidents. The third was infected from the intestine during life, a malignant growth of the rectum ulcerating into the internal iliac vein and producing symptoms of malignant œdema in the right thigh. The patient died in less than 24 hours afterwards. He also discussed the portals of entry and the difficulty of differentiating the pathogenic anaerobes.—Dr. Warrington Yorke read a note on the Pathology of Lesions of the Cornea and Skin in Trypanosomal Infections. Reference was made to the close similarity that existed between syphilis and trypanosomiasis. Three goats and a horse inoculated subcutaneously with a strain of trypanosomes derived from a case of human trypanosomiasis all developed interstitial keratitis. In two of the animals the condition was of transient character. The corneæ became densely opaque and subsequently cleared again in the course of a few days. The condition was indistinguishable from severe interstitial keratitis of syphilitic origin. Rabbits infected with the same parasite exhibited marked changes in the skin. That of the face and eyelids was usually the first to be involved. The skin and subcutaneous tissues became œdematous and indurated and later there was considerable loss of hair. In severe cases the whole of the skin of the back was bald and greatly thickened. Sections of the tissues were examined in different stages of the disease with the object of ascertaining the nature of the morbid processes. The pathological changes in the cornea and the skin were essentially the same, and the course of events appeared to be somewhat as follows. In early lesions parasites were present in the tissue spaces. This was followed by an œdematous condition of the part with a more or less marked degree of leucocytic infiltration and some new vascular formation. In the cornea the lesions were, with a single exception, confined to the substantia propria, which was in severe cases about twice as thick as that of a normal eye. In one case the cornea was three times as thick as normal, and the morbid processes were not confined to the substantia propria, but had involved Bowman's membrane, and the anterior epithelial layer was separated from the substantia propria by inflammatory exudation. The epithelial cells themselves stained badly and were in parts completely disintegrated. In some cases the parasite had disappeared from the tissue, and with their disappearance there was a tendency of the part to recovery. Attention was drawn to the fact that such lesions as those mentioned were essentially due to the local multiplication of the specific parasite, and were not merely dystrophic or toxic manifestations.—Dr. J. Grimshaw confirmed the accuracy of Dr. Yorke's observations, for he had seen the goats and the microscopic specimens.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Feb. 3rd, Dr. A. Christy Wilson, the President, being in the chair.—Dr. E. F. Trevelyan opened a discussion on the Diagnosis and Treatment of Tuberculosis, especially its pulmonary form, presenting a brief and rough summary of 561 cases of phthisis treated in the Leeds Consumptive Institution. An early and certain diagnosis was most important, as the disease could only be healed in its early stages. The importance of careful physical investigation of the chest was reflected in the more recent development of the examination of the extreme apices of the lungs as seen in the apical percussion methods of Krönig and Goldscheider, as well as to a less extent in the use of radiography. The lightest possible percussion gave the best results. The use of solvents (hot alkalies, antiformin) might, perhaps, in a few cases facilitate the examination of the sputum. Tubercle bacilli could sometimes be obtained in the sputum after a tuberculin injection by employing Holt's method. Dr. Trevelyan now used the skin test (von Pirquet's) extensively and the conjunctival less. These reactions did not localise the lesion, but where an organ, &c., was suspected they became of importance. The subcutaneous test was the most valuable owing to its focal reaction. The chest and the sputum should be carefully examined while it was proceeding. For rough purposes of prognosis cases might be divided into—(*a*) those in the early stages of the disease and susceptible of complete healing; (*b*) those whose health might be so re-established that they could return to work; and (*c*) those who would never work again. Early cases and curable cases were not necessarily synonymous terms. Not only were the early cases benefited by proper hygienic treatment (open-air methods), but the worst features of the later disease were much mitigated under it. No drug was of any real permanent service against the disease itself, and drugs should be reserved for, and sparingly used in, the relief of really troublesome symptoms and complications. During the past two years Dr. Trevelyan had used tuberculin rather extensively, first by the mouth and later almost exclusively by subcutaneous injection. By proper individualisation he maintained that no harm could be done and some benefit obtained in almost any stage of the disease. Careful clinical observation of each case, in his opinion, sufficed. He had seen improvement in febrile phthisis by the use of even smaller doses than the small doses usually employed. He was against the ambulatory tuberculin treatment of phthisis unless previously initiated in an institution. This did not so much apply to some other forms of tuberculosis which he had treated with favourable results in ordinary out-patient practice. In conclusion, some remarks were made upon early diagnosis and treatment in relation to the social aspects of phthisis. The importance of the tuberculosis dispensary as the centre of the scheme for dealing with phthisis was emphasised, as well as the instructional uses of consumptive institutions.—Dr. F. W. Eurich drew attention to the necessity of finding suitable work for the poorer patients who were returned from sanatoriums and were unable to resume their former employment. He emphasised Dr. Trevelyan's remarks and the value of Goldscheider's method of light percussion in the early diagnosis of phthisis; he thought there was necessity for a more accurate conception of the relation of the lung to the chest wall, and particularly of the position of the apex. He thought that, on the whole, percussion was the better method than auscultation in the detection of early disease. He had had excellent results in the examination for tubercle bacilli from sputum by using a modification of the antiformin method in which an ether and acetone mixture was employed.—Mr. J. F. Dobson made some remarks on the value of tuberculin injection, principally in relation to surgical forms of

tuberculosis. During the last three years he had seen considerable improvement in a large number of cases. In many cases of tuberculous glands of the neck the improvement had been general as well as local. He started with small doses of T.R. at fortnightly intervals, the patients attending in the out-patient department. For the last six months he had used bacillary emulsion, and on the whole thought the results were better than those given by T.R. In treating glands of the neck in this way it was necessary that the preliminary treatment—the removal of carious teeth, adenoids, and the correction of otorrhœa—should be attended to, otherwise it was practically useless to give tuberculin. In other cases, such as bone tuberculosis and certain joint lesions, he had also seen improvement.—Dr. G. W. Watson thought that in regard to night sweats there was some periodicity to be found in their occurrence, and they were not entirely prevented by open-air treatment. They coincided, not infrequently, with an exacerbation and spread of the disease, and often denoted a mixed infection.—Cases and specimens were shown by Dr. Trevelyan, Dr. R. A. Veale, Dr. M. Coplans, Mr. Dobson, Mr. M. J. Stewart, and Professor A. S. F. Grünbaum.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Feb. 3rd, Dr. Phineas S. Abraham, the President, being in the chair. The evening was devoted to pathological exhibits. Among those shown were the following:—Dr. J. A. Coutts: 1. Heart from a case of Malignant Endocarditis in a child aged 5 years. 2. Heart from a case of Endocarditis in an infant aged 2 months. 3. An Infantile Stomach with Pyloric Stenosis from a case in which gastro-jejunostomy had been performed; the pylorus only admitted the passage of a bristle. 4. Extreme Fibrosis of Lung in an infant aged 15 months.—Dr. J. M. Bernstein: 1. Hypernephroma (operation specimen). 2. A specimen from a case of Ulcer of the Pylorus with perforation into the liver, and abscess in the liver; excision; healing; death from pneumonia. 3. A specimen from a case of Obstructive Jaundice, non-malignant; great dilatation of the bile and pancreatic ducts. 4. A Thymus Gland weighing 833 grains from a boy aged 14 years.—Mr. L. A. Bidwell: 1. Primary Carcinoma of the Liver. The specimen was removed from a man aged 64 years. On opening the abdomen the tumour was found to be circumscribed with no evidence of secondary infection; it was excised. The bleeding points were ligatured, and the "V"-shaped wound was brought together with catgut-sutures which stopped the bleeding. The patient did well for a week, but then developed broncho-pneumonia from which he died. 2. A specimen from a case of Carcinoma of the Transverse Colon fungating through the umbilicus.—Mr. Donald J. Armour: 1. Primary Carcinoma of the Appendix. 2. Polycystic (Congenital Cystic) Kidney.—Mr. W. McAdam Eccles: 1. Fibrolipoma from the forehead of a man. The patient was shown at the last clinical meeting of the society, when it had been diagnosed as probably dermoid. 2. Alveolar Sarcoma of the Ovary from a girl aged 11 years. The tumour weighed 6 pounds.—Mr. J. A. Cairns Forsyth: 1. A Kidney with a Cyst which contained 22 Uric Acid Calculi (the cyst did not communicate with the pelvis of the kidney). 2. Kidney showing Hydronephrosis from Malposition of the Ureter, which sprang from the upper part of the pelvis. 3. Liver showing extreme Cirrhosis not due to alcohol.—Mr. Francis F. Muecke: A Cast of the Laryngeal Ventricles from a patient with malignant disease of the larynx.—Mr. J. E. R. McDonagh: Microscopic slides showing the Causative Organisms of Balanitis Erosiva et Gangrenosa, a condition very rare in this country, but frequently found in Austria and Hungary. It is easily cured with peroxide of hydrogen.—The President: A man with Tuberosities on the Face and Hands, probably epitheliomatous.

MANCHESTER MEDICAL SOCIETY.—A meeting of this society was held on Feb. 1st, Dr. A. Emrys Jones, the President, being in the chair.—Mr. L. Savatard communicated the following cases:—1. Xeroderma Pigmentosum in a female aged 42 years. The condition, first noticed three years ago, had gradually progressed and was not affected by the variations of season. No warty or other growths had as yet arisen. Microscopical examination of a pigmented area showed, in addition to a mass of pigment in the epidermis and cutis, marked disturbance and atrophy of the basal cells. Attention was drawn to the striking similarity between this condition and X rays dermatitis with subsequent malignant growths. 2. Lupus Vulgaris of long standing with (*a*) papilloma, and (*b*) epithelioma or scar tissue. 3. Cutaneous Neurofibromatosis, with General Fibrosis of the Peripheral Nerves, in a man aged 25 years. There was no family history of this or any allied condition. This was his fourth attack, the first appearing five years ago after an attack of acute rheumatism. The cutaneous lesions of the previous attacks had entirely involuted. The lesions were most numerous on the trunk; the larger ones, not exceeding 1·5 centimetres in diameter at their base, were hemispherical and sessile, with a bluish transparent look. Many of the smaller ones presented a purpuric appearance. A section of a small tumour (kindly made by Dr. C. Powell White) showed it to be a soft fibroma of the terminal filaments of the cutaneous nerve pushing upwards into the cutis and displacing the sweat and sebaceous glands.—Mr. J. W. Smith read a communication on the Treatment of Carcinoma Recti.

# Reviews and Notices of Books.

*Dyspepsia, its Varieties and Treatment.*[m] By W. SOLTAU FENWICK, M.D. Lond. London and Philadelphia: W. B. Saunders Company. 1910. Pp. 485. Price 13*s*.

DISORDERS of digestion form a large proportion of general medical practice, yet much misunderstanding exists as to the classification of these disorders and the principles upon which their treatment should be based. These difficulties are no doubt due, as Dr. Fenwick suggests, in great measure to a disposition to regard dyspepsia as a substantive disease dependent upon a primary failure of the gastric functions, whereas in a considerable proportion of the cases the symptoms originate in the intestines, and may ensue from a derangement of the liver, pancreas, or bowel. We have not expressed the above opinion exactly in Dr. Fenwick's own words, for although there is doubtless much to be said in favour of the views he expresses, we consider that he rather depreciates the part which the stomach plays as the prime seat of digestive disorders. For instance, in our opinion, the following sentence requires modification: "Moreover, a disturbance of digestion in the stomach itself is rarely due to a primary disorder of that viscus, but is usually a consequence of serious disease of another and perhaps remotely situated organ of the body." Then he adds, "The truth of this apparent paradox will be appreciated when it is remembered that the majority of the secretory, motorial, and inflammatory affections of the stomach result from the failure of some other organ to execute its proper functions." That the stomach is frequently unjustly blamed as the sole originator of indigestion may be admitted, but we believe the statement we have quoted to be too sweeping in its character. Nevertheless, the warning it contains is a sound one, and it behoves the practitioner to make a careful examination of the patient, and exhaustively to consider the symptoms before arriving at the conclusion that the stomach is the seat of the primary trouble.

The classification of dyspepsia which Dr. Fenwick adopts is a good one, and will be found especially useful for purposes of treatment. His description of the symptoms of each variety is easy to follow, and much information will be obtained by a study of his remarks. We would especially draw attention to the explicit manner in which the differential diagnosis is discussed. Unless an accurate diagnosis is made the treatment must incline to be empirical, whereas, in order that success may follow, rational therapeutic measures are essential. In this direction this work will be found to be of considerable value, and practitioners may derive many useful hints as to the best manner in which to treat their patients, both as regards diet and

drugs. The various mechanical methods also receive due notice.

---

*Die Physiologie und Pathologie des Wochenbettes, für Aerzte dargestellt.* Von Privat Docent Dr. F. FROMME, Oberarzt der Königlichen Universitäts-Frauenklinik zu Halle-a.-S. Berlin: S. Karger; London: Williams and Norgate. 1910. Abt. 31; Tafeln 2. Pp. 256. Price 8.40 marks; bound, 9.60 marks.

THE prominent part played at the present day by the practice of antisepsis and asepsis in the care of lying-in women, and the importance of the occurrence of various septic processes resulting from the neglect of such practice, are well illustrated by the publication of this book, and also by the fact that of the eight volumes of von Winckel's "Handbook of Midwifery" a bulky volume of no less than 1000 pages is devoted to these matters. The correct treatment of the large majority of confinement cases consists in the intelligent application of the principles of antisepsis. By these means childbirth has been robbed of most of its dangers, and that a book of 256 pages should be devoted to such a subject is further proof, if any were wanted, of the paramount urgency of this treatment.

Dr. Fromme has written a very interesting work dealing with the normal and abnormal puerperium. In the first half of the book he discusses the physiology of this period, including under this head the processes of involution, the secretion of the milk, the symptoms of the puerperium, and the care of the mother and of her baby. The second, and more special, portion of the book deals in a very complete manner with the pathology of the lying-in period. The normal and abnormal organisms met with in the genital tract are described, and also the diseases which may result from their presence. This part of the book is very good indeed. The various forms of infection are clearly described, and the author shows in a clear manner the distinctions between the many septic conditions which may follow delivery.

In considering the treatment of cases of so-called sapræmia due to the retention of portions of the placenta or membranes in utero, Dr. Fromme is strongly in favour of the least possible interference. If necessary he advocates the removal of pieces of placenta or membranes with the finger, but he deprecates curetting or the application of strong antiseptics to the uterine cavity. He quotes with approval Professor Winter's conclusions, who maintains from his own observations that the spontaneous expulsion of portions of placenta is much safer for the patient than their artificial removal. The author describes in detail, for particulars of which we must refer our readers to the book itself, a method which he believes can be relied upon for determining whether a hæmolytic streptococcus is merely a harmless saprophytic or a virulent pathogenic organism. In the treatment of cases of septic infection he lays great stress on this distinction, since upon it he bases to a large extent his treatment and his prognosis. Unfortunately, these observations have not been substantiated by other observers, and we have therefore at present no reliable method of distinguishing between saprophytic and pathogenic streptococci in the genital tract. The chapters devoted to a consideration of the various forms of puerperal infection, and the differences they present in accordance with the variety of organism present, will well repay careful study. Besides sections dealing with the effect of the gonococcus in the puerperium and of the rarer organisms associated with some septic processes, there are others treating of puerperal tetanus and diphtheria. Other conditions considered are infections of the urinary tract and of the breasts, while the concluding chapters treat of the hæmorrhages and the psychoses of the puerperium.

The whole work forms an excellent monograph. It contains a large amount of information, and if we are inclined to disagree a little with some of the author's love of minutiæ in, for example, his antiseptic precautions, this is a good fault. On the other hand, we do not believe that "the rational puerperium," of which he is a strong advocate, will last as long as this book, on the production of which Dr. Fromme is to be congratulated.

*Oxford Medical Publications. Clinical Pathology in Practice, with a Short Account of Vaccine-therapy.* By THOMAS J. HORDER, B.Sc., M.D. Lond., F.R.C.P. Lond., Medical Registrar and Demonstrator of Morbid Anatomy (late Demonstrator of Pathology and Junior Demonstrator of Practical Medicine) at St. Bartholomew's Hospital, Physician to the Great Northern Hospital and to the Cancer Hospital. London: Henry Frowde and Hodder and Stoughton. 1910. Pp. 216. Price 7*s.* 6*d.* net.

IT is expressly stated in the preface that the aim of this book is not to serve as a laboratory text-book, but to present the practitioner with a brief survey of the scope and usefulness of modern pathological methods as applied to the diagnosis and treatment of disease. To apply laboratory methods practically to the investigation of cases certain information is necessary, including a knowledge of the materials to be studied, the manner of collecting them, and the value of the results obtained. Dr. Horder's book is well calculated to supply this information and should prove of real value to those practitioners who desire to apply the methods of so-called clinical pathology intelligently and usefully. In a valuable suggestive introductory chapter Dr. Horder is careful to utter a warning against any tendency to neglect the physical methods of examination of the patient or to exaggerate unduly the rôle of the clinical pathologist and the value of the information he supplies. He urges the necessity of a close and mutually helpful relationship between the clinician and the pathologist.

After the necessary apparatus required for the collection of material for investigation has been briefly described, a useful account is given of the method of blood culture. The indications for this procedure, the technique of its performance, and the interpretation of the results obtained are all dealt with concisely and in a practical manner. The histological examination of the blood, the methods of enumerating the corpuscles, and of estimating the percentage of hæmoglobin are next considered, and the significance of the results of such examinations is discussed. The characters of the blood in the chief varieties of anæmia are briefly described, and the causes of leucocytosis and of leucopenia are enumerated and differentiated from one another.

The methods of pathological investigation of diseases of the lungs and pleura are dealt with under three separate headings, the first being the examination of the sputum, the second the examination of fluids obtained by pleural puncture, and the third the investigation of material obtained by direct puncture of the lung. The characters of the sputum in various diseases of the respiratory tract are clearly described and differentiated from one another. In connexion with pleural puncture the chemistry, cytology, and bacteriology of the different pleural exudates are considered. An interesting and critical account of the bacteriology of empyemata is a useful feature of this section. The substance of the chapter on puncture of the lung for diagnostic purposes has already been published in our columns by Dr. Horder,[1] and we have commented on this procedure, which he strongly recommends, in an annotation.[2] A careful description of the method of lumbar puncture and its use in diagnosis and treatment is afforded in a chapter

[1] THE LANCET, Nov. 6th, 1909, p. 1345.
[2] Ibid., p. 1366.

devoted to this subject, which we may mention as one of the best in the book.

Separate chapters are devoted to infective conditions of the nose, mouth, and throat, infective diseases of the urinary tract, the results of joint puncture, and the examination of the fæces. The diagnosis of tuberculosis and its specific treatment are next dealt with, and clear accounts of the diagnostic tuberculin reaction and its recent modifications are here included. Lucid descriptions of the principles and mode of carrying out certain specific reactions, such as Widal's and Wassermann's tests, are then given. An interesting chapter on fever without physical signs affords a valuable illustration of the practical application of the methods to be applied in the study of obscure febrile conditions. The use of bacterial vaccines in treatment is dealt with in a thorough, common-sense, and practical manner in the last two chapters. The questions of dosage and of the intervals between successive injections are discussed in the light of Dr. Horder's own experience. He regards the control of vaccine treatment by repeated determinations of the opsonic index as unnecessary. The use of stock vaccines is also briefly discussed. In general we may say that the recommendations given are practical, and no exaggerated claims are made in regard to the value of the method.

We have read Dr. Horder's book with interest, and can recommend it as a useful practical handbook.

*Salvarsan ("606"): Its Chemistry, Pharmacy, and Therapeutics.* By W. HARRISON MARTINDALE, Ph.D. Marburg, F.C.S.; and W. WYNN WESTCOTT, M.B. Lond., D.P.H., His Majesty's Coroner for North-East London. London: H. K. Lewis. 1911. Pp. xv. + 77. Price 5*s.* net.

A DEFINITE general opinion as to the value and trustworthiness of the preparation "606" can hardly be said yet to have formed, and though the amount of evidence in its favour largely surpasses the evidence opposed to it, yet at present it cannot be expected that the new remedy should be accepted without question. This book, written by the authors of the well-known "Extra Pharmacopœia," contains a very useful collection of the substance of most of the papers which have appeared on the subject of "606." The work commences with an account of the chemistry of the drug; the therapeutic results obtained are also described, the question of dose is considered, and the mode of introduction discussed. The untoward results which have occurred are referred to and the contra-indications are given. An interesting section is that devoted to some special communications which have been addressed to the authors during the preparation of the work. These are all from London authorities and are well worthy of perusal.

On the whole the book gives the impression that the authors do not regard the drug with favour, though it is difficult to point to any individual expression to this effect. They are thoroughly conversant with the chemistry of the substance and its allies, but they are possibly somewhat handicapped in preparing the work by the fact that they appear to have no personal knowledge of the clinical application of the drug.

---

*Physiological Principles in Treatment.* By W. LANGDON BROWN, M.A., M.D. Cantab., F.R.C.P. Lond., Physician to the Metropolitan Hospital; Medical Registrar and Demonstrator of Physiology, St. Bartholomew's Hospital. London: Baillière, Tindall, and Cox. 1910. Pp. 392. Price 5*s.* net.

IN THE LANCET of Dec. 26th, 1908, we published a review of the first edition of this work, in which we expressed the favourable opinion we had formed as to its merits. After again perusing this volume we cordially repeat the praise to which we then gave utterance.

The alterations in this edition are mainly in matters of detail, though additions have been made to some of the sections. In the remarks on the movements of the stomach, the results obtained by X ray examination with from ½ to 2 ounces of bismuth oxycarbonate suspended in milk or gruel are detailed. Reference is also made to the investigations of Cannon and Hertz, which have added considerably to the knowledge of the passage of food through the stomach. Some addition has also been made to the chapter on uric acid and the purin bodies, endogenous purins being more fully considered. The chapter on intestinal intoxications has also been largely re-written. Attention is given to the subject of vaccine treatment of intestinal intoxications. It is suggested that a plate culture may be made from the stools, and the effect of the patient's blood in agglutinating or destroying the more definitely pathogenic organisms tried. If a positive reaction be obtained with one or more of these a vaccine may then be prepared. Additions have been made to the chapter on irregular action of the heart, and the remarks on this subject are some of the most interesting in the book.

We can recommend this work to the attention of our readers, and believe that it will continue to receive a wide acceptance at the hands of the profession.

---

1. *Lippincott's New Medical Dictionary.* A Vocabulary of the Terms Used in Medicine and the Allied Sciences, with their Pronunciation, Etymology, and Signification. By HENRY W. CATTELL, A.M. (Laf.), M.D. (U. of P.). Freely illustrated with figures in the text. London and Philadelphia: J. B. Lippincott Company. 1910. Pp. 1108. Price 21*s.* net.
2. *The Practitioner's Medical Dictionary.* An Illustrated Dictionary of Medicine and Allied Subjects, including all the Words and Phrases Generally Used in Medicine, with their Proper Pronunciation, Derivation, and Definition, based on Recent Medical Literature. By GEORGE M. GOULD, A.M., M.D. Second edition, illustrated. London: H. K. Lewis. 1911. Pp. 1043. Price 18*s.* net.
3. *The Illustrated Medical Dictionary.* A New and Complete Dictionary of the Terms Used in Medicine, Surgery, Dentistry, Pharmacy, Chemistry, Nursing, and Kindred Branches, with the Pronunciation, Derivation, and Definition. By W. A. NEWMAN DORLAND, A.M., M.D. Fifth edition, revised and enlarged. London and Philadelphia: W. B. Saunders Company. 1909. Pp. 876. Price 19*s.* net.

1. WITH the multiplication of medical words comes a multiplication of medical word-books. The latest addition to the already large list of medical dictionaries is one compiled by Dr. Henry W. Cattell for the J. B. Lippincott Company, which has answered our expectations in furnishing information on such words as we have tested it with. We are pleased to find that the author has adhered to the more classical spelling of those words in which there seems to be in America a decided determination to effect an abrupt cleavage with the past—such words, for instance, as anæmia, diarrhœa, iodide, sulphur, which many who seem to think that change is synonymous with progress and reform would have us spell anemia, diarrhea, iodid, sulfur. The book is not too bulky to handle with ease, and has a thumb index.

2. Gould's "Practitioner's Medical Dictionary" in its second edition is practically a new work. Great pains have been taken to include most of the new terms that have been coined in such profusion during the last decade or so, and the metric system equivalent has been added where weights and measurements are given, especially in the matter of doses. The additions and changes of the new (U.S.) Pharmacopœia have been included, also the B.N.A. anatomical nomenclature. The author's interesting Notes Concerning the History of Lexicography, from the preface to his Dictionary of New Medical Terms, is republished. The fact that over 200,000 copies of the author's various medical

dictionaries have been scattered all over the civilised world certainly testifies to a wide appreciation of his labours.

3. "Dorland's Illustrated Medical Dictionary," now in its fifth edition, is too well known to need much comment, further than to state that the entire book has been rewritten, many of the definitions revised, and more than 2000 new terms have been added, many of which appear herein for the first time in any dictionary. A special feature has been made of those biological words which are now appearing with hitherto unwonted frequency in medical literature, especially physiological and pathological, while the B.N.A. nomenclature and the latest classification of proteins have been adopted. This work is illustrated with several admirable coloured plates.

The unsatisfactory part of these dictionaries—a minor one certainly, as compared with the importance of definitions and explanations of the new terms in medicine and the allied sciences that are being so continuously coined, to the confusion and bewilderment of the reader—lies in the orthography and pronunciation. To the former we have already referred when speaking of "Lippincott's Dictionary." The latter is more naturally in a state of flux than the former ought to be; still, even there it is frequently mispronunciation that gives rise to wrong spelling. Pronunciation is said to be a matter of good usage. But what constitutes "good" usage? The method of the few scholars who really know and are careful, or that of the majority who are as a rule neither well informed nor careful? In America the usage of the majority, irrespective of scholarship, in Great Britain the usage of the more scholarly, irrespective of the number, seems to carry the day.

## LIBRARY TABLE.

*Photography in Colours.* By GEORGE LINDSAY JOHNSON, M.A., M.D., B.S. Cantab., F.R.C.S. Eng. London: Ward and Co. 1910. Pp. 143. Price 3*s.* 6*d.* net.—The rapid advance made in photography in colours has been so remarkable that Dr. Lindsay Johnson has thought it desirable to write a monograph rather than to revise this section of his previous work on "Photographic Optics and Colour Photography." He deals with the fascinating subject in a simple but comprehensive manner, and shows repeatedly that his advice and comments are founded on ripe experience of all the methods. The colour photographs which adorn the book prove that he is an able practitioner of the art; they are somewhat harsh in colour contrasts and therefore lacking in the delicate refinements which are obtained more successfully in other ways, but it must be remembered that they are employed here to some extent as diagrammatic models. After a preliminary historical review the author compares the eye with a camera and draws some analogies between colour photography and normal and defective vision. He shows how the luminosity curve of the retina may be approximated by the panchromatic plate, the application of pinacyenol to the plate causing an extension of the curve of sensitivity towards the red end of the spectrum. The theory underlying Lippmann's interference method, three-colour photography by additive and subtractive methods, and the multitudinous single-plate colour processes, is very lucidly described, and is worth reading by those who do not propose to practise the art. It is illustrated by admirable diagrams and photographs, which afford much assistance to obtaining a clear understanding of what is really more confusing than actually complex. The chapters on the practical details of the working of single colour-screen plates and photographic colour printing will be of the utmost help to beginners. A final chapter on Kinematography in Natural Colours is followed by an appendix where details of developing and tables of times of exposure and so on are given.

*Vaccine Therapy: its Theory and Practice.* By R. W. ALLEN, M.D., B.S. Lond., late Clinical Pathologist to the Mount Vernon Hospital, &c. Third edition. London: H. K. Lewis. 1910. Pp. 277. Price 7*s.* 6*d.* net.—Considerable alteration has taken place in this book since we reviewed the first edition in 1909. If we remember rightly, the title was originally "The Opsonic Method of Treatment," but this feature has now dropped out from the place of honour. The change corresponds with a change in the author's views as to the importance of this particular procedure, for he now believes that opsonic estimations are not needed as a routine measure in all cases of inoculation, though owning the accuracy of the method, when used by an expert, for the measurement of the degree of immunity existing in a patient. He perhaps hardly allows sufficient weight in this question to the adverse opinions which have been expressed by some very careful and competent observers. It can hardly be doubted that vaccine treatment has, if we may be pardoned a colloquialism, "come to stay." Hence such a presentation of the whole subject as is contained in Dr. Allen's book must be welcome. The most noteworthy extension of the field for this procedure which is at present in view is the use of vaccines in acute infections, such as enteric fever and pneumonia. Good results are claimed by several observers in both these diseases, and the method is certainly worthy of trial. We observe that the author advises the use of autogenous tuberculins as well as of vaccines of this nature in other diseases; but good results are also claimed for the employment of bovine tuberculin in human cases. The use of vaccines in the "carriers" of infection, such as enteric fever, is also likely to lead to valuable results. By way of minor criticism we may question why a case of carbuncle is placed under the heading of "Periostitis and Osteomyelitis" (p. 94), and note the term bacillus Caucasicum—surely a "false concord"—for the Bulgarian bacillus, and such curiosities of expression as "similar results to when introduced subcutaneously" and "any affection soever" (for "whatever"). The book is well printed and got up.

*Travail de l'Amphithéâtre d'Anatomie des Hôpitaux: Recherches d'Anatomie Chirurgicale sur les Artères de l'Abdomen. Le Tronc Cœliaque.* Par PIERRE DESCOMPS, Prosecteur des Hôpitaux. With 97 figures in the text. Paris: G. Steinheil. 1910. Pp. 205. Price 10 francs.—This monograph upon the arteria cœliaca has been compiled by M. Descomps from special and minute dissections of 50 subjects, and from a study of the literature. A detailed account is given of the variations of the origin of the trunk and the distribution of its terminal branches, and the labour has not been undertaken merely as an exhaustive study in descriptive anatomy, for, as the author points out, a surgical interest attaches itself to the anomalies in distribution of the branches of this artery. The work is a laborious and complete inventory of the variations of a definite arterial trunk; and it will remain as a permanent work of reference for the specialist. The author is greatly to be commended for his illustrations, for his 97 figures are all examples of a type of diagram in which so many French publications excel. These little drawings, though mostly having no pretence to a more than diagramatic representation of the part depicted, are carefully and artistically drawn. They are accurate and simple, and the fact that they were intended only as diagrams has not been taken by the draughtsman as an excuse for careless drawing. This point is one worth noting, for the appearance—and utility—of so many modern English works is spoiled by the inclusion of careless and inaccurate figures the faults of which are excused on the grounds that they were only intended as diagrams. Every figure given by

M. Descomps is clear and is carefully drawn, and even those that depict the most unimportant trifles are done with an altogether excellent attention to accurate detail. They add greatly to the value of a book which from its nature can never be one of very general interest, but which is a monument of conscientious work upon which the author is to be congratulated.

*A Manual of Nursing.* By MARGARET FRANCES DONAHOE. London and New York: D. Appleton and Co. 1910. Pp. 489. Price 7*s.* 6*d.*—Miss Donahoe tells us in her preface, where she speaks of herself, that "the mistakes and crudities are her own," and this frank confession makes us all the more sorry to have to say that there are many mistakes. For Miss Donahoe's chemical, physiological, and medical knowledge is, judging by her own statements, very imperfect. Where she does know her subject she knows it well, for her accounts of such nursing matters as washing a patient, passing a catheter, making a bed, and dusting a ward are good and clear. But in other matters her teaching is sadly incorrect, and so is her Latin. For instance, on p. 102 she talks of "the glans clitoris," and on p. 112 of "pruritis," while on p. 286 she uses "cilia" as a singular noun. These errors are, however, harmless, but the same cannot be said for the following. On p. 66, "Urine has a peculiar ammoniacal odor," a statement which is certainly not true of normal urine, and again on the same page, "Urine is fluid unless it contains quantities of mucus or blood or albumin, when, if left standing, it may be almost jelly-like in consistency." We do not think that albumin by itself will make urine jelly-like. On p. 126 we are told, "A high temperature with a dry skin is not so dangerous as the same temperature with a wet skin," a statement which, taken generally, is not true. On p. 203, plaster of Paris is stated to be "calcium sulphide." On p. 323 she says, "Often associated with heart disease is rheumatism. This attacks the joints, flying about from one joint to the other, causing intense pain, but leaving the joints uninjured." As a whole, we cannot conscientiously recommend this book, though, as we have said above, there are portions of it which are useful and accurate.

*Feeding and Care of Baby.* Issued by the Society for the Health of Women and Children. Dunedin: Mills, Dick, and Co. 1910. Pp. 144. Price 1*s.*—This little book is a compilation on the subject of infant management, which has been issued by the Society for the Health of Women and Children, New Zealand. Although the work is anonymous, it appears from the context that the medical authorities in connexion with the Karitane Baby Hospital are responsible for the work, and it would be almost impossible to compress more correct and authoritative advice on the whole subject into a smaller number of pages. It is quite clear that all the best works have been consulted and quoted, not always, however, with due acknowledgment. The book just misses excellence, owing to want of orderly arrangement and the proper marshalling of facts. There are much repetition and constant change in the type. Very often most important facts are printed in the smallest type, while those of less importance are more conspicuous. The illustrations are excellent, but crowded haphazard into the text. A good and experienced editor with very little trouble could convert this medley of facts into a valuable and practical guide for mothers and others who are concerned with the management of infants.

*The Care of Infants and Young Children in Health.* By MILDRED M. BURGESS, M.D. Lond. London: H. K. Lewis. 1910. Pp. 72. Price 1*s.* net.—This useful little manual, while intended for all interested in the healthy upbringing of children, is especially likely to prove of service to those attending courses of lectures on infant care. It follows the syllabus of the infant care course of the London County Council and deals with breast and substitute feeding, the general conditions influencing growth and development, baths, the clothing of babies and young children, the treatment of emergencies, and ventilation.

*Formation of Character.* By Rev. J. B. S. WATSON, M.A. Second edition. London: H. R. Allenson. Pp. 115. Price 1*s.* 6*d.*—Mr. Watson's position as chaplain of His Majesty's Prison, Brixton, must certainly have afforded him ample opportunity for studying the relation between the plight of those derelicts with whom as a prison official he came into contact and their perversion or want of character. There can be no doubt that there is a lack of discipline in the bringing up of the young of the present day that is causing vast uneasiness as to the future in the minds of many thoughtful persons. At present, those who would give us "royal roads" are having things more their own way than they are entitled to, and the result is a sentimentalism that would eliminate from modern "educational" methods whatever happens to be irksome or distasteful to the child, seeking to cause it to lay hold on information—knowledge is not the word—by methods of play. If the acquisition of information, or even knowledge, were the sole or the main object of education such methods would, perhaps, adequately achieve their end. But if the chief aim of education is the formation of character by self-discipline and self-control, these qualities must be initiated by discipline and control from without, for it is doubtful if any man ever learned to exercise discipline and control on himself until he had first learned to submit himself to discipline and control at the hands of others. The book before us consists of a preface by the Rev. G. P. Merrick, formerly Chaplain-Inspector of His Majesty's Prisons; a foreword on Industry, by Mr. Andrew Whitlie; and chapters by the author respectively on Character, Courage, Temperance, Industry, and Reverence and Self-Reverence, each describing and illustrating factors in the formation of character and the attainment of moral culture. In regard to reverence, the author quotes the saying of George Eliot, "The first condition of human goodness is something to love. The second something to reverence." And later he writes: "Having for years visited and interviewed men and youths whose character has suffered through the commission of some form of crime, I venture to affirm that the lack of due reverence for one's own self and for the self of others is the prime cause of the great proportion of the cases that have come under my notice and my care." The book is illustrated by anecdotes well calculated to attract the attention of young readers, and is pervaded by a high moral tone of which the religious foundation is plainly but not obtrusively set forth.

*A Text book of General Bacteriology.* By EDWIN O. JORDAN, Ph.D., Professor of Bacteriology in the University of Chicago and in Rush Medical College. Second edition, thoroughly revised. Fully illustrated. London and Philadelphia: W. B. Saunders Company. 1910. Pp. 594. Price 13*s.* net.—The first edition of this work was published so recently as 1908 and was reviewed at length in this journal.[1] In the present issue the author has "corrected a few errors, repaired some omissions, and added several new sections." The changes are not, however, very serious, and though the book has been lengthened by some 26 pages, about 13 of these are accounted for by a greatly improved index. Though the book is written to a great extent on lines usually followed by text-books of bacteriology which are intended for medical students and is perfectly well adapted for the use of such students, yet the desire of the author has been to treat the

[1] THE LANCET, March 13th, 1909, p. 769.

subject on broad lines and deal with it as part of a general liberal scientific education and not as the technical training of a specialist. The chief changes introduced in this edition consist in the inclusion of a description of the iron and sulphur bacteria, and in the chapter on diphtheria of a section on the methods of concentration of antitoxic serum. The section on bacteria in art and industries has been lengthened by the addition of paragraphs on bakery fermentations, the retting of hemp, and on the bacteria which cause destruction of cellulose. There are some additions to the diseases of plants which are described, and there is a short discussion on the vexed question of the entrance of organisms through healthy plant tissues. The section on diseases of doubtful bacteriology now includes the recent work on anterior poliomyelitis. Several diseases to a large extent peculiar to North America are mentioned. Amongst them is Rocky Mountain spotted fever, but we do not observe that any mention is made of the possible relation of the disease to typhus. The appearance of the book and the printing are, as in the first edition, good. The selected illustrations also are well reproduced.

*The Taxonomic Value of the Microscopical Structure of the Stigmal Plates in the Tick Genus Dermacentor.* By C. W. STILES. Bulletin No. 62. With 43 plates. Hygienic Laboratory, Treasury Department, Washington, U.S A. 1910. Pp. 72. —The author of this brochure, Dr. C. W. Stiles, is well known in this country as well as in his own for his investigations upon these and other parasitic animals, including more particularly the tapeworms. We have, therefore, to consider a work by a naturalist well qualified to instruct us upon a matter which, at first sight perhaps trivial, is really of great importance. The markings and sculpturings upon certain of the hard parts of these small and parasitic arachnida are of themselves doubtless a justifiable contribution to zoology, inasmuch as this facilitates the identification of species, and thus leads to a general view of the number and distribution in the world of these little-noticed animals. But in addition to this the subject has a greater importance by reason of the fact that ticks are now well known to convey disease from animal to animal upon which they are parasitic. Thus, their minute investigation is not only of theoretic but of great practical weight. For, as in the case of mosquitoes and malaria, it is not every tick which conveys disease; and the object is to concentrate our destructive energies upon those species which are really guilty. The first step to be taken is therefore clearly to have at hand plain directions as to the characteristics of the several forms; and Dr. Stiles makes a distinct contribution towards this desired end in the pamphlet before us. His editors, the Treasury Department of the United States Government, have done well in showing a great liberality in the matter of plates which obviously render it easy, and without which perhaps barely possible, to identify the different forms. To this end there is a lavish series of plates not only showing details of the microscopic build of the stigmal plates, with which the author is principally concerned, but showing also magnified and coloured illustrations of the entire animals in the case of a few species.

*Hazell's Annual for 1911.* Edited by HAMMOND HALL. London: Hazell, Watson, and Viney. Pp. lix.–592. Price 3*s.* 6*d.* net.—This well-known member of the great group of periodical reference books that are practically indispensable to a man of affairs to-day made its appearance somewhat late this year on account of the General Election, but the work gains by the inclusion of a biographical list of Members of the House of Commons now sitting, with statistical tables and summaries of important announcements by the party leaders during the election. Many questions of the day—political, socio-economic and imperial—have their respective issues outlined. There is practically no phase of interest in modern life which escapes its notice. Many new subjects have been introduced and the old ones brought up to date.

*The Probationer.* By A. M. IRVINE. London: S. W. Partridge and Co. Price 2*s.* 6*d.* Pp. 300.—This is an amusing and brightly written story, and the author, we should say, has a first-hand acquaintance with the scenes which she describes. All the same, we should not have thought it possible that a raw probationer would be let loose in the ward of a children's hospital and simply told to make the children's beds without the smallest information as to what they were suffering from. Naturally enough, she took her first patient out of bed, a proceeding which did not commend itself to the authorities, since the child had pneumonia. The heroine of the tale is blessed with a sense of humour, and is in no way blind to her own shortcomings. She had plenty of pluck, and the way in which she conquers her own ignorance and stupidity and wins the favour of all, including a fascinating house surgeon, is quite readable. The story may be recommended to all young women who are thinking of taking up nursing as a calling. Not the least amusing portions of the story are those in which blunders in simple cookery are described, when amongst other matters the efforts of the probationer to boil milk ended in disaster.

*The Cookery Annual for 1911 and Year Book of the Universal Cookery and Food Association.* Seventeenth year of issue. Edited by C. HERMAN SENN, G.C.A., &c. London: Food and Cookery Publishing Agency. 1911. Pp. 166. Price 1*s.*—More than a fair proportion of illness in this country is attributable to a defective knowledge of catering, including cooking; and this is especially true among the poorer classes. The Universal Cookery and Food Association was established in 1885 to promote and encourage the advancement of the art of cookery in every grade among all classes of the community, Her Majesty Queen Alexandra being chief patroness. This book, edited by the managing director and chief secretary of the association, contains much interesting (and some curious) information concerning the association and kindred organisations; also a series of menus for three meals on every day of the year.

## JOURNALS AND MAGAZINES.

*Journal of Anatomy and Physiology.* Conducted by Sir WILLIAM TURNER, K.C.B., ALEXANDER MACALISTER, ARTHUR THOMSON, ARTHUR KEITH, and ARTHUR ROBINSON. Vol. XLV., Part II. January, 1911. London: Charles Griffin and Co. Annual subscription, 21*s.*, post-free.—Of the ten papers included in this number no less than three are devoted to the vertebral column and ribs. Dr. E. Barclay-Smith describes in full detail the anomalous vertebral column of an ancient Egyptian, presented to the Cambridge University Museum by Professor G. Elliot Smith. In this peculiar spine a great disturbance of the normal arrangement is seen, both in the anatomical form and in the numerical distribution of the various types of vertebræ. The first cervical vertebra is fused to the occipital bone (one free vertebral segment is assimilated to the skull), and this absorption of the first free element is obviously correlated with the general disturbance in the distribution of the units of the column. There is a lack of fully described vertebral columns, some regions of which show anomalous types of vertebræ; for too often the anomaly is described without relation to the remainder of the vertebral elements. This careful record of an anomalous column is therefore a welcome addition to the literature, for it is only from such complete records that a future generation of anatomists may collect data for drawing

conclusions as to the real causation and meaning of these strange variations. Dr. W. L. H. Duckworth describes a curious variety of the first thoracic vertebra; but, unfortunately, the condition of the other units of the vertebral column cannot be recorded, and the anomaly must stand only as the recorded variation of an individual vertebra unassociated with anything that might tell of its causation or its significance. The same author also describes a case of osseous tumour of the frontal region of the skull, the chief interest of which lies in its association with certain abnormalities in the form of the pituitary fossa. Professor E. Fawcett, in a paper entitled "Some Notes on the Epiphyses of the Ribs," points out the discrepancy among the views of various anatomists concerning the number and situation of these centres; and he shows that the actual epiphyses vary in different members of the rib series. The epiphyses of the upper six ribs he finds to be somewhat different in their distribution from those of the lower six, and from this fact he adduces support for Dr. A. Keith's findings concerning the different rôles in respiration played by the upper and lower ribs. A paper by Professor E. J. Evatt deals with the development of the prostatic gland in the female and the homologies of the urethra and vagina in the two sexes. The writer reconstructs the urethra and vagina of a human female fœtus of 3½ months, and from the reconstruction and the study of sections of fœtal material he has come to the conclusion that the distribution of the prostatic remnants in the female points to the correctness of the views regarding the development of the vagina put forward some years ago by Berry Hart and by Wood Jones. He has given fresh evidence for the claims of these workers that the vagina is formed as a solid downgrowth, and not by septal division of the cloaca or by fusion of the Müllerian ducts. That a third independent worker has established the truth of these strange transformations of the visceral openings should place the matter beyond dispute. Since the understanding of the malformations of the visceral openings depends upon a knowledge of the manner of their development, it is to be hoped that these methods will become incorporated in ordinary gynæcological teaching. One other embryological paper is that of Mr. Douglas G. Reid, and it deals with the fœtal disposition of the peritoneum. Mr. A. B. Appleton gives a very detailed account of the brains of a Madrassi Hindu and of a Tamil, which are preserved in the Cambridge University Museum. Professor A. F. Dixon gives an account of a case from the dissecting rooms of Trinity College, Dublin, in which three kidneys were present. Mr. Percy Sargent has a paper entitled "Some Points in the Anatomy of the Intracranial Blood Sinuses," and Dr. S. E. Whitnall one dealing with "A Ligament acting as a Check to the Action of the Levator Palpebræ Superioris Muscle."

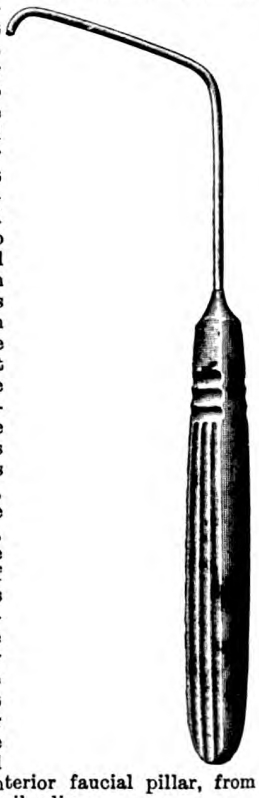
*Edinburgh Medical Journal.*—The February issue of this magazine contains several papers of exceptional interest. Dr. Ashley W. Mackintosh, Dr. A. W. Falconer, and Dr. A. G. Anderson write on congenital family cholæmia, otherwise called acholuric family jaundice, and describe a case in a boy aged 7 years. The condition is held to result from undue fragility of the red corpuscles, owing to which they break up in the circulation with formation of bile pigment which may be found dissolved in the serum, but which does not appear in the urine. With this condition may be contrasted that of erythræmia described by Dr. H. L. Watson Wemyss on a later page of this journal, which may, perhaps, be produced by diminished destruction of red cells, though another view attributes it to an affection of the bone-marrow. Mr. Alexander Don writes on operative procedures about the knee-joints and advises large incisions for opening this cavity. Dr. Charles Melland discusses conditions associated with enlargement of lymphatic glands, and Dr. R. Cranston Low writes on fungus infections of the finger-nails, which may be due to ringworm, to favus, or to an unknown species of fungus.

*Dublin Journal of Medical Science.*—In the January number is published an inaugural address by Mr. W. I. de C. Wheeler on the treatment of fractures by ancient and modern methods, in which he points out the advances due to Lucas-Championnière, who was followed by Mr. Arbuthnot Lane. He points out the dangers run by surgeons in connexion with the treatment of fractures, if they depart in any way from the accepted routine, in the event of an action being brought against them on account of a supposed defective result; and also the incapacity of the ordinary tribunals to decide questions involving these lesions in connexion with the Workmen's Compensation Act. Sir John Moore records a series of interesting clinical experiences, including cases of pneumonia and enteric fever, and one of staphylococcal septicæmia, which improved under vaccine treatment.

# New Inventions.

## A HOOK TO RETRACT THE ANTERIOR FAUCIAL PILLAR DURING "MORCELLEMENT" OF THE TONSIL.

THE numerous observations about the alarming hæmorrhages that follow the removal of the tonsils with the guillotine have contributed to extend the practice of morcellement of the tonsil with suitable forceps. This method is very easy to execute, it being possible to avoid bleeding and pain with the new chemical substances for local anæsthesia. The forceps used for "morcellement" exercise not only a cutting, but also a crushing action, which reduces and hinders hæmorrhage. In order to simplify the grasping of the tonsil a hook is often used, with which the faucial pillar covering its anterior surface is retracted. With the instrument usually used the faucial pillar is drawn out, but the assistant's hand masks the operation and limits the free movements of the surgeon. I have introduced with the best results a new type of hook, which was made for me by Mr. Spinelli, 2, Mazzini-street, Turin, Italy. The handle is 9 centimetres in length, the shaft 10 centimetres, and the hook 1 centimetre. The end of the instrument is rounded, so as not to damage the mucous membrane. The two portions of the shaft form an angle of 80°. By the use of this instrument the assistant's hand does not obstruct the surgeon. Moreover, the angular disposition of the hook and handle allows only a moderate lateral traction to be put upon the anterior faucial pillar, from behind which the hook does not easily slip.



Turin, Italy. CIRO CALDERA.

A BRISTOL CENTENARIAN.—A Bristolian named John Bevis died on Feb. 6th aged 104 years. He had for some time been an inmate of the "Home of the Sisters of the Poor" in Bristol, where he died.

# THE LANCET.

*LONDON: SATURDAY, FEBRUARY 18, 1911.*

## The Value of the Medical Museum.

TIME has again brought round the date of the delivery of the Hunterian Oration at the Royal College of Surgeons of England. There may be some who feel surprise that the College should commemorate every two years by the Hunterian Oration the life and work of JOHN HUNTER, while many other surgeons who in their day were attached to the College, and who performed services of the first importance to the cause of science, receive no such posthumous recognition. On what is this singularity of treatment based? Certainly upon no inclination to underrate the services to science of the other celebrated men who have worked for her in this country; the College, we may be sure, appreciates to the full the great benefits which have resulted to humanity at large from the self-sacrificing labours of many of the surgeons of the past, while the Hunterian orators do not claim that the work done by JOHN HUNTER was of such a kind as to mark him off from all others. But in this particular manner JOHN HUNTER stands pre-eminent—he was almost the first to advocate and practise systematic research either in biology pure or in biology as applied to medicine. He was in our view actually the first to grasp the potentialities underlying an extension of knowledge in the direction of comparative biology whereby the light thrown on disease in man could be made brighter by observations on disease in the lower animals; he was the first to recognise that life and its methods are one both in the lower animals and in man, and to see that the simplest, the most ready, and the most rapid method of advancing our knowledge of the processes of health and of disease in man would be by the systematic observation of these processes as they occur in the lower animals, possibly by creating experimental differences of condition suitable to supply the deficiencies of our knowledge. He recognised long before the days of DARWIN the oneness of man with the rest of the animal kingdom, and saw also that the morbid processes of plants might be similar in nature to, and comparable to, the morbid processes of man himself. Being thus the apostle of experimental and comparative medicine, he fully deserves that the medical profession should record from time to time their sense of obligation to him for what he did and for what he taught. The frequent recurrence of the Hunterian Oration is fully justified.

We do not propose here to refer to the individual discoveries and inventions, great though they were, for which HUNTER was responsible, they have been set out time after time by his biographers; rather we would point to the spirit with which he conducted the work which he set himself to do. He wanted facts. He did not underrate the forming of theories to account for phenomena that had been observed; he himself was ready enough to try to link together the various apparently disconnected phenomena by the chains of theory, and not the less so because he knew that at any moment a theory of itself might suggest the lines along which future researches should proceed. But he objected, and strenuously expressed his objection, to the building of theories without a firm basis. Only too commonly, in HUNTER'S time as before and since, theories have been formed apart from facts, and, again only too commonly, if any attempt has been made to find a connexion between the theories and the facts, the facts have been modified and deformed to accord with the theories. HUNTER insisted on two things—on the need for exact and repeated observation so as to eliminate the possibility of mistakes, and the need for accurate record of the observations made, so that they might be available for reference and comparison at other hands. We know, for we have the testimony of WILLIAM CLIFT, HUNTER'S famous pupil and assistant, that his master made most careful notes of all he did, and his personal records filled hundreds of pages in volumes which are, alas, now no more. The story of their destruction is too notorious to need repetition, but we see from his remaining work that HUNTER was ever ready to give credit to all his predecessors for the observations which they had made and for the facts they had recorded, though he only valued the work of others in so far as it consisted of faithful records of what had been seen and done. Observations of conditions which cannot be repeated have to be received on the mere statement of the observer, but when a condition is capable of experimental production, when its repetition is possible as need arises, it passes into the realm of fact. HUNTER knew this, but he knew also that it was possible to record observations so that the basis of any statements made concerning them could be readily seen, and it was to accomplish this purpose that he formed his museum. Before his time pathological museums must have been so comparatively small as to be quite unimportant. Few public bodies possessed museums of any form relating to science. The early lecturer on medicine or surgery at the medical schools generally possessed "a museum" for his own purposes, but such "museums" were as a rule small, and not necessarily made up of interesting specimens from cases which had fallen under the observation of their possessor. These collections were sets of objects for teaching and were often sold to his successor by the lecturer when his time came to cease giving lectures. HUNTER was the first to conceive the idea of a scientific museum in the modern sense, and to see that in such an institution there might be collected a tangible and largely indestructible basis upon which to rear pathological structures of all sorts. He endeavoured to bring together specimens of every sort illustrating facts in zoology, botany, and human anatomy, showing diseases of various kinds whether occurring in men, in animals, or plants. His specimens were not merely those which he prepared for himself or which came in his way in the course of his practice as a surgeon; he demanded and obtained for his great scheme the interest and collaboration of many other observers. His oft-quoted letters to EDWARD JENNER form but one series of correspondence which he had

with many friends in many parts of the country. Each one he employed to find, so far as time and opportunity would permit, specimens for his museum and to collect facts for his general work. When any point seemed doubtful and he was unable to fill up for himself the lacuna in his arguments he would write to one or other of his correspondents and entreat them to observe the facts or to ascertain the truth of some previous report. But he spared not himself. Working early and late, rising at daybreak and going late to rest, he devoted every moment not absorbed by his professional work to the perfecting of his museum. Successful as he was in practice, he valued that practice mainly for the power which it gave him to enlarge his museum and thus to gain more systematic knowledge; and the spirit with which he himself worked he inculcated in others. He asked no one else to do what he was not able and willing to do himself to aid in the discovery of the truth and the augmentation of human knowledge. HUNTER died poor. Apart from his museum and his notes he left almost nothing; and by his will we know that he looked to the purchase of his collection by the Government to provide for the family which he left behind him. And though it was a time of war, of storm and stress, and of enormous calls upon the public funds, the Government even of that day, with claims upon it whose urgency we in these softer times can hardly guess, was able to spare the small sum required to buy HUNTER'S museum.

And so it came to pass that the Hunterian Museum, great beyond all comparison in HUNTER'S day, was a few years after his death entrusted to the keeping of the Royal College of Surgeons of England, a State trust as the President of the College has pointed out. On the basis of JOHN HUNTER'S museum the authorities of the College, assisted by such conservators as WILLIAM CLIFT, RICHARD OWEN, JOHN QUEKETT, WILLIAM FLOWER, CHARLES STEWART, and ARTHUR KEITH, have formed a collection of human anatomy, both normal and pathological, of comparative anatomy, both of plants and animals, far surpassing any similar collection in the whole world. JOHN HUNTER'S museum was large—enormous for his time and for the work of one man—but the museum of the Royal College of Surgeons of England is the greatest collection of its kind in the world; its completeness and its value can only be appreciated by a careful and prolonged inspection. At a large total cost of money, during the many years which have elapsed since the museum was first entrusted to its care, the College has nourished the collection as it deserved to be nourished; it has been liberally supplied with funds, and above all things it has been wisely and jealously supervised. For all who are capable of knowing good work when it is done, of appreciating the value to science of such a collection as the museum, must acknowledge that the College could not have done more than it has done: it could not have more worthily carried out the work it has undertaken. What would have been the surprise, the pleasure, and the pride of JOHN HUNTER if he could but see the museum into which his own collection has grown. Mr. EDMUND OWEN'S oration on last Tuesday (see p. 417) was what those who know him might have expected; it was a clear, forcible, and eloquent picture of the greatest of biological teachers, one of the most original of British surgeons, and the first real exponent of the value of the experimental methods in medicine.

## The Education of Crippled Children.

THE national importance of the medical profession is perhaps in nothing more evidenced than in the fact that its outlook and scope have long ceased to be limited to the alleviation of individual suffering, or even to the prevention thereof by the inculcation of personal hygiene; that they have over-passed even the field of disease-prevention in the present by stimulating to effective action the public perception; that as each man's well-being depends not only on his own obedience to the laws of health but on that of others also, each has an interest in the healthy living of all, from which perception has arisen scientific sanitation; and that now these energies are directed to the guidance of the recently awakened public foresight in securing the utmost physical, mental, and moral efficiency for the coming race. In warfare every disabled soldier not only robs the fighting line of an effective unit, but if he remains in it he hampers and impedes the efficiency of the remainder. A wise general, therefore, looks for the prompt removal of such to the rear outside the sphere of action, where he may, if possible, be promptly restored to the effective strength in the field or, failing that, be cared for at the least possible tax on the effectiveness of the fighting force. Life, not only the life of the individual, but still more the life of a nation, is a warfare, and those who are born physically below the average, or who become so in their earliest years through the ignorance or indifference of those on whom they are entirely dependent for care and support, are the nation's future non-effectives. For this reason the adjustment of their relation to the education system, whereby each individual is trained ultimately to play his part in the nation's warfare, is highly important.

In a recently issued pamphlet, "The Care of Invalid and Crippled Children in School,"[1] Mr. R. C. ELMSLIE has republished a series of five lectures, the first of which was delivered in the course of advanced school hygiene at University College, London, the other four having been delivered to the school nurses attached to the London County Council invalid schools. They are now modified in detail and somewhat added to to suit a wider public than that for which they were originally written. While all the lectures are of public utility, the first especially is of far-reaching significance and deserves to be widely read. The writer aims to define the term "physical defect" as applied to school children and as used in the Elementary Education (Defective and Epileptic) Act of 1899. In this term he would include, not only all deformities and diseases of the bones, joints, and spine, which obviously cripple the child, but also all general defects of physique and chronic illnesses, anything which continuously interferes either with

[1] The Care of Invalid and Crippled Children in School. By R. C. Elmslie, M.S. Lond., F.R.C.S. Eng., Medical Officer (Invalid Schools) London County Council Education Committee. London: The School Hygiene Publishing Co., Limited. Price 1s.

attendance at school or with the ability of the scholar to follow in full the ordinary school routine. The duties of the school medical officer he divides into separating such children, supervising them, whether in ordinary or special schools, both at work and at play, advising their natural guardians when treatment is necessary, and supervising the instruction that may properly be given to them. Much has already been done to provide education under suitable conditions for certain classes of such subjects, but the great need is for the provision of resident hospital and sanatorium schools, where children who require prolonged hospital care (as, for instance, in the case of orthopædic patients or subjects of bone tuberculosis), children during prolonged convalescent treatment, or phthisical children, can have their education carried on simultaneously with proper physical care. Mr. ELMSLIE very cogently points out, in answer to an objection which is sometimes urged, especially in regard to the education of permanently crippled children—viz., that they are of no value to the community, and that by helping and educating them we are enabling them to survive and perpetuate their defects in their children—that they do survive whether we help them or not, and that by training them to make the most of themselves in spite of their limitations we lessen the burden on the community through workhouses and infirmaries; and, secondly, that in most cases such defects are acquired, and in the present state of our knowledge the inheritance of acquired defects is to be regarded as not proved and improbable. The early admittance of children to schools and the careful medical inspection of infant schools would lead to prompt discovery during the remediable stage of many cases of tuberculous bone disease, for these frequently originate before ordinary school life starts, when the vagueness of the accompanying phenomena (which by no means generally include, as is commonly supposed, easily recognisable characters, such as pain and deformity) makes the conditions appear trivial to the parents. Finally, crippled and defective children, more than others, especially need an efficient technical training to minimise their disabilities and enable them to compete with the healthy and well-informed; and the earlier manual instruction is given the more easily is dexterity attained, so that the loss of many initial years in elementary education is an even greater drawback to the defective than to the normal child.

## The After-Care Association.

THE annual meeting of this society was held on Feb. 8th, under the presidency of Mr. H. D. GREENE, K.C., one of the honorary Commissioners in Lunacy—a notable incident, because persons of such delicately and importantly responsible positions do not often preside over esoteric functions. The presence in the chair of a Lunacy Commissioner on this occasion gave the cachet of recognition and authority to an institution founded and maintained in a true philanthropic spirit, and affords us a reason for bringing before our readers in a prominent manner its very valuable design. The association had a very small beginning in the year 1869—though it was not until 1897 that it assumed a corporate form—when the Rev. HENRY HAWKINS, at that time the learned chaplain of the Colney Hatch Asylum, put into active motion an idea he had formed of the advantage, even the necessity, of following up some of the persons discharged as cured with the view of aiding them during the period between the return to home and the capacity for resuming occupation. Mr. HAWKINS'S idea was only slowly taken up, but through dint of his advocacy, aided by the persistent efforts of the great Lord SHAFTESBURY, Lord MEATH, a few medical men, and an energetic band of ladies, the movement attained considerable *vis viva*, and it now is generally recognised as a charity with great scope of usefulness. Owing to the pressure on accommodation in the county asylums it is necessary to discharge "recovered" patients as soon as possible, but there is no doubt that in many instances the "recovery" is not firmly established; it may be technically true, but it does not satisfy the ideas of those who know all about the case and are familiar with the relapses that so frequently occur in those whose convalescence is prematurely interfered with through having to return to work at once without having gone through an annealing process, so as to become tempered to the arduous surroundings of their avocations after leaving the fostering care of the institution. There are many other reasons why "recovery" in these discharged cases is only a comparative term. Patients, with the concurrence of their friends, are anxious to get free from the appanages of restraint, however graciously they may be exercised; they think that the shorter the time they are away from home the less serious will their illness be thought to have been; they know that in their absence the rest of the family is reduced to straits which make it imperative that they should resume at the earliest date the care of those from whom they have been sequestrated. And then again, there is a legal difficulty in detaining in an asylum persons who have technically become well mentally, even though it may be well known that the repair to the breach of continuity is of a very fragile nature and may be easily disrupted unless time is given for its consolidation.

The outside public views with distrust the employment of persons who have just been discharged from asylums; if they knew that a period of probation had elapsed between the time of leaving the institution and that all had gone well in the meantime they would have more confidence in resuming relationships. So cognisant of the advantages of a probationary interval are the authorities of many asylums that they actually do discharge for varying lengths of time, granting money allowances in the meanwhile, many patients who are really free from the symptoms for which they were originally detained, but who are not thought sufficiently recovered to resume work at once; but it must be remembered that during the period of "absence on trial" these people are still considered to be "patients" and remain under the force of their certificates, whereas under the auspices of the After-Care Association they are unfettered and have full sense of responsibility. As an economic factor this association has been of much use in preventing early convalescents from relapsing, thus becoming again chargeable to the rates and going through the misery of

a second attack. In this connexion it might be worth consideration by the Poor-law authorities how far they could expand or adopt the scheme of the After-Care Association, and so form as convalescent homes for their just recovered cases judiciously chosen places where, free from the incubus of certificates, a short time could be spent in perfecting a process barely completed. Private benevolence has often preceded State interference and shown the necessity for it; and under some such plan, though there would be a small extra burden on the rates, a saving would ultimately accrue owing to the diminished number of relapses, whilst the proper care and the support of the family would be ensured on the return home with much greater certainty of permanence than there is at present. These homes would be almost self-supporting, because if aptly chosen (and they need not be large) the smallest amount of supervision would be required and the necessary in- and out-door work would be done by the residents.

A further extension of the sphere of the After-Care Association is that for small weekly sums the bureau nominates houses into which can be received persons whose faculties are not quite up to the average, but yet who are capable of being usefully employed and made comfortable when superintended by people who have had previous experience in this direction. At one of the meetings a member of the association recommended that there should be a fore-care scheme as well as an after-care for persons who were on the verge of an illness which might be made abortive by some timely retreat. Such a scheme is feasible; it would make possible to the poor what is at present almost entirely confined to the well-to-do classes—viz., the privilege of being "voluntary boarders," an arrangement by which numbers of people get well without the formality and the odium of certificates. A boarding-out system has never found great favour in this country, but it has great potentialities, and we look forward with interest to see whether the After-Care Association can act as pioneer in a movement of this description, as it has certainly been in procuring aid for convalescents whose chances of permanent soundness were before imperilled. There are many ways of assisting necessitous people besides grants of money, and one of the salient features of this association is that by personal and particular supervision the individual's needs and powers are thoroughly understood and catered for. Most of the medical superintendents of asylums, than whom none know better the danger of exposing just recovered patients to the worries attending the restarting the machinery of social obligations, are active members of the association and have developed branches in the different counties with which they are chiefly concerned. In the absence of extraneous support of any kind the society is dependent on voluntary contributions and on the precarious amounts contributed by the committees of asylums who avail themselves at times of the resources which have been exploited by this band of charitable workers, but we think that a far greater development of the work is possible. A rich person in search of a movement which for its expansion requires a large donation could not easily find an object fraught with greater advantages to a particularly unfortunate class of people than by giving support to this humanely conceived organisation. The Commissioners in Lunacy have always strongly supported the claims of the association, to which, indeed, they hand on certain moneys, called the Commissioners' Fund, which are at their disposal for purposes similar to those of the association.

# Annotations.

"Ne quid nimis."

## SCHEDULE FOR SCOTTISH CENSUS OF 1911.

BY the courtesy of the Registrar-General for Scotland, we have received a copy of the Census schedule which will be distributed to the householders of Scotland on the appointed day in April next. As we have not yet seen either the English or the Irish schedule we are uncertain to what extent uniformity will be observed respecting the details of information demanded in the three divisions of the United Kingdom. But, from a cursory examination of the document before us, we assume that some modification at any rate will be needed in order to adapt the questions to the local requirements of England and of Ireland. We note that in the Scottish schedule the names of certain occupations are included which are peculiar to Scotland. For example, the terms "United Free Church Minister," "Episcopalian Clergyman," "Crofter fisherman," "Crofter road surfaceman," would hardly appear in an English or an Irish schedule. Again, the attempt to ascertain the proportion of the population speaking Gaelic alone, or Gaelic and English together, would scarcely be made on this side of the Tweed. On one point in particular the Registrar-General deserves congratulation. Under the heading "particulars as to marriage" he has inserted several columns designed to ascertain the degree of fertility among married women. Thus the householder or head of the family is requested to state, with respect to each married woman entered in the schedule: (1) The number of years elapsed since marriage; (2) the number of children born alive; (3) the number still living. If these facts can be ascertained with approximate accuracy it is obvious that material will be available for the investigation of problems regarding fertility and fecundity which will prove of great sanitary as well as economic importance. We trust and believe that similar information will be forthcoming for the other divisions of the United Kingdom. One word by way of criticism. We observe that the whole of one side of the Census sheet is occupied by the schedule itself, and that on the back of the sheet a large number of "instructions" are printed for filling up the columns headed "profession or occupation." After careful perusal of the schedule we confess that we ourselves should have difficulty in filling up certain of its columns, even with the help of the appended instructions; and we doubt whether the majority of working-class householders upon whom the duty is imposed will fully realise their responsibilities in this regard. When Dr. Grimshaw was Registrar-General of Ireland the schedule was directed to be filled up, not by the often illiterate householder, but by the enumerator, who was usually a police officer. It was Dr. Grimshaw's deliberate opinion that the Irish system led to the making of Census returns infinitely more accurate than could be hoped for under either the English or the Scotch system then in vogue, which was that of relying upon the sagacity of the average householder or head of a family. We shall be interested to observe how the difficulty to which we have referred is dealt with in Scotland.

## THE PERAMBULATING ORGAN AND THE DECOY CHILD.

CHILDREN carried upon organs played in the streets are frequently an object of commiseration to passers-by, more particularly in weather as cold as that which has recently prevailed, and pity for the child no doubt often takes the somewhat illogical form of pence bestowed upon the persons in charge, who are presumed to be destitute parents. The practice is one which all must condemn on the child's account, and many will sympathise with the child and the constable referred to in the recent newspaper reports of a prosecution at the Marylebone police court. In this instance it may be that the charge was not rightly framed, but the result appears unfortunate. A constable arrested a man and woman who were playing an organ in the street with their child, aged 21 months, with them, the child being described by the constable as seated in a box and "shaking with cold." Mr. Plowden, before whom the parents were brought at the Marylebone police court, observed that "there are a number of people who derive pleasure from hearing an organ," to which the constable replied by calling attention to the presence of the child, when Mr. Plowden answered, "Well, there is no harm in people having a child with them." The constable: "But it was cold." Mr. Plowden: "We all suffer from that. It is legal to play an organ if no one objects. There is absolutely no reason for charging these people." It may be, as has been suggested, that the charge on which the parents were brought before the magistrate was one which could not be sustained, but it is difficult to agree with the apparent meaning of the magistrate that there is no harm in conduct such as that described. It would also seem to come near to justifying a charge of exposing a child in a manner likely to cause unnecessary suffering or injury to health under the twelfth section of the Children Act, 1908, or, perhaps, under the fourteenth section of the same Act, for that children carried about by organ-players are so treated, as a rule, in order to increase their "earnings" can hardly be questioned. The fourteenth section is as follows:—

(1) If any person causes or procures any child or young person, or having the custody, charge, or care of a child or young person, allows that child or young person to be in any street, premises, or place for the purpose of begging or receiving alms, or of inducing the giving of alms, whether or not there is any pretence of singing, playing, performing, offering anything for sale, or otherwise, that person, shall on summary conviction, be liable to a fine not exceeding twenty-five pounds, or alternatively, or in default of payment of such fine, or in addition thereto, to imprisonment, with or without hard labour, for any term not exceeding three months.

The people who derive pleasure from hearing an organ presumably enjoy the same sensations when the instrument is played by a man unaccompanied by his wife and by an infant "shivering with cold," and when he takes these with him it is not unreasonable to suggest that he does so in order to excite sympathy, or in other words to attract alms. It is possible, however, that the fourteenth section is only intended to apply where the child takes a more active part in inducing the giving of alms than it does when it "sits in a box," and that the pretence of playing must be made by the child itself and not by persons who accompany it.

## PREVENTION OF PAIN AFTER AMPUTATION BY THE INJECTION OF SOLUTION OF QUININE.

THE value of quinine as a local anæsthetic is only beginning to be recognised, and this is strange, for the drug itself has been known 90 years. In the January number of the *American Journal of Surgery* occurs an article by Dr. V. Pleth and Dr. V. W. Pleth of Seguin, Texas, on the value of a solution of quinine for preventing the pain in the stump after amputation. It is used as follows. When the amputation is completed and the vessels tied the solution of quinine is injected into the main nerves and around them, and after the wound is closed about three ounces of the solution are injected into the tissues composing the stump. The patient suffers no post-operative pain. The solution employed consists of a 0·5 per cent. solution of bisulphate of quinine. The treatment appears to have no injurious influence on the tissues. The application of the drug has also been extended to the treatment of fractures. With a strong gold-plated needle the quinine solution is forced in between the fragments of the fracture and several syringefuls are also injected around the fracture, and in about 15 minutes reduction can be made without causing pain. The writers have also used quinine in operations on the rectum for fistula, hæmorrhoids, and fissures. Severe pain following rectal operations is in this way obviated. There are several advantages in using quinine for local anæsthesia; it is non-toxic and therefore can be used freely; it can be sterilised by boiling without losing its efficacy; and, lastly, it is cheap.

## THE INTERNATIONAL HYGIENE EXHIBITION, DRESDEN, 1911.

AN organisation which aims at success must satisfy public opinion in several respects. In the first place the promoters must produce evidence of capability and earnestness. In the second they must deliberate with care, and expend time, energy, and money in casting their mould and in laying their foundations. Next there must be proof of the importance to the public of the undertaking, and, lastly, means must be adopted to inform the public of the details of the scheme. The administration of the International Hygiene Exhibition, Dresden, 1911, has fulfilled all these conditions, and we may safely assert that success is assured. The promoters include the most eminent scientists in the German Empire; each committee (and there are many) is doing real earnest work, carefully planned and maturely developed, and expenditure is not begrudged in accomplishing this work. We have on previous occasions pointed out in THE LANCET the educational and scientific importance of this undertaking to mankind. With regard to publicity also the administration has left nothing to chance. For the past 19 weeks a two-page pamphlet called "Hygieia" has been issued widely, in which the reader is informed of the progress of the exhibition preparations and in which his interest in the various branches of hygiene and public health is awakened and kept awake by skilfully penned popular articles. We have now before us the first issue of a more enterprising publication which is to appear in monthly numbers and which bears the title "Hygiene." The contents of No. 1 are varied, interesting, and instructive, and include a brief historical account of the development of the exhibition; an article on the architecture of the buildings now in the course of erection, which will reflect credit to the 21 skilled architects who are devoting their time and energies to the task; a brief account of some of the congresses which are to be held in connexion with the exhibition, and a number of illuminating essays on subjects which will be dealt with. The publication is well got up and most excellently illustrated. Attention may be directed to the picture of the Russian Government Pavilion which in true national architecture promises to be a great feature of the exhibition. Close to this building the French Government is to erect the French National Pavilion, while the space between—the choicest site of all—is still being reserved for the British Pavilion. It is a deplorable fact that our Government has not accepted as its duty the task of erecting and equipping this building, but thanks to the conspicuous energies of the British National Committee,

and particularly of Sir Thomas Barlow, the chairman, and Lord Ilkeston, the treasurer, there is good prospect that the sum required to carry this project through without the Government will be collected in time. Support has already been received from several corporations, notably those of Glasgow, Manchester, and Liverpool, from several of the City Companies, and from many prominent scientific firms. Much still remains to be done, and there is but little time to do it; but now that nearly one-third of the amount has been secured the officials are confident that the remainder will be forthcoming. The appeal which is being made calls on all to subscribe small or large amounts to uphold the reputation of Great Britain as the pioneer and leader in hygiene and to further feelings of real friendship between England and Germany, which have already been questioned by the German press. Cheques should be made payable to Lord Ilkeston, treasurer of the British Executive Committee, International Hygiene Exhibition, and sent to 47, Victoria-street, London, S.W.

## HÆMOLYTIC JAUNDICE WITH HÆMOGLOBINURIC CRISES.

To the brief series of cases hitherto recorded in which the production of jaundice associated with paroxysms of hæmoglobinuria has been traced to hæmolysis an important addition has been made by Dr. A. A. Hijmans van den Bergh of Rotterdam, and recorded in the *Revue de Médecine* for January. The subject of this observer's investigations was a man aged 47, whose family history was innocent of any similar event and who had never suffered from any serious illness. In 1899 he first consulted a medical man on account of an attack which was pronounced to be a catarrhal jaundice, though the fæces were normal in colour and the urine contained much urobilin but no bilirubin. In 1904 he expectorated blood, but no other evidences of pulmonary disease were manifest. The first bout of hæmoglobinuria occurred in 1905, and since that date the attacks have returned at irregular intervals and with a widely varying intensity. No cause for these attacks could be discovered; they were not confined to cold weather and they did not follow the ingestion of any particular food. They lasted one day in some instances, in others several days. Each attack was accompanied by an aggravation of the anæmia and jaundice, which persisted in some degree even between the attacks, by a sense of oppression in the præcordium, and by pain referred to the hypogastrium during the passage of the hæmoglobinuric urine. For some days after a paroxysm the urine contained albumin and casts. The excretion of urobilin, always supernormal, was also increased during the attack and immediately after it. The spleen was not enlarged. Examination of the blood showed a hæmoglobin content of 50 per cent., an erythrocyte count of 2,970,000 per cubic millimetre, and a corpuscular picture characterised by no changes other than those of a secondary anæmia. In one of the attacks the hæmoglobin stood at 40 per cent. and the red corpuscles at 1,156,000 per cubic millimetre. The patient's corpuscles showed a normal resistance to the ordinary hæmolytic tests, and at the same time the serum was proved to contain no abnormal hæmolysins. Dr. van den Bergh therefore had recourse to certain methods of hæmolysis which he had found useful in the investigation of hæmoglobinuria "a frigore." These experiments yielded results of some interest. The first series of tests showed that the corpuscles of the patient were destroyed by the patient's serum and also by a normal serum at body temperature in the presence of carbon dioxide vapour, but not in the presence of air or at laboratory temperature (except in one test where the normal serum exercised a hæmolytic action at 16° C. in the presence of $CO_2$). Another series of similar tests gave the same result as far as the action of the patient's serum was concerned; but the control serum showed a hæmolytic action in air or in $CO_2$ at 16° C. as well as at 37° C. These experiments prove that for the case under consideration the hæmolytic factor was corpuscular fragility; and they suggest the advisability of further investigations bearing on the activation of this tendency to hæmolysis such as was achieved in Dr. van den Bergh's experiments by the substitution of carbon dioxide for air, and the use of a temperature raised to that of the body.

## A FALLACY ABOUT COFFEE.

IN looking about for an explanation of the recent cases of poisoning at Dalkeith, in which the poison was conveyed through drinking coffee, the suggestion has been made and widely circulated that there is a certain coffee-bean which in given circumstances throws off a deadly poison. This information will come as a surprise to all toxicologists. We know of no such coffee-bean, and we very much doubt its existence. It is a great pity that newspapers cannot guard themselves against such statements. The confidence of the public is thereby seriously disturbed and a needless fear is sown in their minds. Apart from scientific investigation, the evidence of experience is completely opposed to the notion that sometimes coffee beans are met with which give off a deadly poison. If coffee contained a volatile poison at all in the sense that the original disseminator of this scare probably had in his mind, it would be thrown off obviously in the roasting. As is well known, a strong infusion of coffee has proved most useful to counteract the effect of poisons, and its use is particularly enjoined when an overdose of a narcotic—e.g., morphia—has been taken. Coffee, in common with most articles of food, may disagree with some people, who soon find that fact out and take care to exclude it from their dietary. But it is innocent of poison and to a great number of people is an undoubted boon. Such people may continue to enjoy their favourite beverage without the slightest fear that for some mysterious reason Nature makes some of the beans poisonous. The widespread publication of the fallacy has been most unfair to the public, besides constituting an obvious injustice to the coffee trade.

## THE TREATMENT OF INCIPIENT PHTHISIS IN EAST LONDON.

IN a report recently presented to the Public Health Committee of the Borough of Poplar, Mr. F. W. Alexander, the medical officer of health, has suggested a scheme for preventing the spread of tuberculous infection, and benefiting, with the hope of curing, cases of pulmonary tuberculosis in subjects who have work to do and are able to undertake it. He suggests the purchase of two or more large houses in the borough with open spaces in the rear, so that huts may be erected in the grounds, and the rooms of the houses utilised for open-air treatment by adaptation of the windows for such a purpose. The rooms could be fitted with apparatus for keeping the air charged with ozone, and used by persons in the incipient stage of phthisis for sleeping purposes at night, whilst attending their work during the day. A short time ago Mr. Alexander put forward a proposal for the purchase by the local public, as a memorial to the late King Edward, of the City of London Union Infirmary (now disused), a building standing upon five acres of ground, conveniently situated in a main thoroughfare of the East-end of London, immediately upon the borders of the boroughs of Poplar and Stepney and within easy reach of Bethnal Green, Hackney,

Shoreditch, and West Ham, which could be used for such a purpose. It is unfortunate that so eminently practical a proposal has not received the local support necessary to put it on foot, for the building might be used also as a tuberculosis dispensary. A combination of the early notification of phthisis, with in suitable cases its immediate treatment, together with good hygienic sleeping accommodation, each patient under his own medical adviser, seems a promising method of capturing and dealing with incipient phthisis amongst men in full and active employment, whom the hospitals and consumption sanatoriums do not reach.

## THE CLIMATIC ADAPTATION OF THE IMMIGRANT.

RACE adaptation to climate has received at various times considerable attention at the hands of Major Charles E. Woodruff, of the Medical Corps of the United States Army, whose views on the question of the harmfulness of excessive sunlight to blondes have met with much opposition, though he appears to have adduced not a little *primâ-facie* evidence in their support. Probably the truth lies, as usual, midway between two extremes. In the *Eugenics Review* for January, he writes some interesting remarks on "The Eugenics of Migrants." He there points out that a character that is of indispensable value in one environment may be so injurious in another that migrants promptly perish. Nearly every species is limited to a very restricted environment, and those which change residence with the seasons are really more restricted than those able to stay behind and resist the changes of weather. The medical profession, he says, is only just beginning to realise that man himself is governed by the same laws of adaptation, and that each type has developed characters which fit it for residence in the place of origin. Four factors in the past have influenced migration. In the earliest times movement was naturally slow, so that evolution could proceed *pari passu;* then social organisation added its prevention of invasion. Later, however, military organisation caused rapid migrations, which have become greatly increased by the rapidity of modern transportation. Major Woodruff discusses adaptation as shown in alteration of pigmentation and weight, and cites the disappearance of the type of northern invaders from the southern lowlands of Italy—of the men, that is, from the north, who were the real authors of the Italian renaissance, the significance of whose Italianised names is often contradicted by their extant portraits. He alludes also to the experience of America, where the blonde type, of which the women sent over from Northern France almost entirely consisted, has nearly disappeared from the St. Lawrence Valley, and entirely so from New Orleans. The blondes in American cities and lowlands, he says, have a higher death-rate from certain diseases than the rest of the population, and tend to disappear, while those in the mountains remain vigorous after many generations. Nature herself carries on among migrants the expensive eugenic movement of killing off the least adjusted. In the meantime those on the way to extinction are less able to struggle for existence, and so furnish more than their due proportion of social parasites. This is the point that must be considered in all eugenic discussions. Migrants should strive to have their children reared in a climate proper to their racial characteristics, even though they themselves have to live elsewhere—a fact with which Anglo-Indians have become familiar years ago. Major Woodruff suggests an investigation among the "failures," the "submerged tenth," in London and all large cities, not only of Europe, but also of America, Africa, and Australia, to decide their prevailing characteristics in each case—whether tall or short, light or dark, over- or under-weight. This may demonstrate that certain types are locally on the way to a final elimination that cannot be prevented by eugenics. He alone is *eugenes*, well-bred, who is of the type adjusted to the place, and the migration streams must continue until each type finds its proper adjustment. The production of a higher mental type depends probably, at any rate in great degree, on first acquiring a physique perfectly adapted to its climatic environment.

## THE ACTION OF DRUGS.

IN a paper read at the February evening meeting of the Pharmaceutical Society Dr. W. E. Dixon, professor of materia medica and pharmacology at King's College, London, discussed the action of various drugs, the object of the paper being to explain the purpose of the pharmacological notes in the British Pharmaceutical Codex. He said that few drugs had attained more popularity lately than compounds of calcium, but if a calcium effect is really needed the drug must be injected under the skin. Similarly, the specific effects of potassium or ammonium salts could only be produced in this way, since their rates of elimination could more than keep pace with their absorption. The local application of opium or morphine in any form was harmless, though of little value in relieving local pain, since the seat of action of morphine was on the central nervous system. Proceeding, he said that quinine was not in any sense a tonic; it was rather an atonic drug; it was a poison to all protoplasm and diminished metabolism. Referring to the organic compounds with the metals, he said experiments seemed to show that none of the organic compounds of silver were superior to silver nitrate, and that the organic compounds of iron mostly derived from blood must first be broken down and digested before absorption occurred. These are a few of the examples selected by Dr. Dixon to give some idea of the scope of the pharmacological notes included in the monographs—notes for which, in his view, some need was certainly felt by medical practitioners.

## REPORT OF THE DEPARTMENTAL COMMITTEE ON CORONERS.[1]

THIS report, which has just been issued as a Blue-book, contains the evidence of certain witnesses recalled and further examined, together with ten appendices, amongst which are a summary and analysis of replies to questions addressed by the committee to coroners of England and Wales, a memorandum on behalf of the London County Council, a memorandum on behalf of the British Medical Association, and the returns for England and Wales of reported deaths under anæsthetics during 1908. The memorandum on behalf of the British Medical Association, after certain introductory paragraphs, is divided into four parts, dealing respectively with death certification, the procedure of coroners, deaths under anæsthesia, and the question of necessity for inquiry into deaths following surgical operations. The memorandum submits a scheme of death certification providing means whereby a medical certificate of death shall be obtained in most cases not certified by the medical practitioner in attendance, leaving the remainder to be dealt with by the coroners, and points out the defects in the present procedure. Questioned upon this subject, 169 coroners replied that they were satisfied with the present system, and 99 coroners stated

[1] Second Report of the Departmental Committee appointed to inquire into the Law relating to Coroners and Coroners' Inquests, and into the Practice in Coroners' Courts. Part III. Cd. 5492. London: Eyre and Spottiswoode, Limited. Pp. 109.

that there were difficulties and the system did not work satisfactorily. This serious division of opinion among coroners certainly justifies the British Medical Association in its desire for amendment of the laws. In regard to medical evidence as to the cause of death, the memorandum rightly states that it is of two kinds: (1) clinical, and (2) pathological, the former being of especial value in the preliminary inquiry when the coroner has to decide whether he shall order a post-mortem examination, and, if so, who shall be ordered to do this. This is a matter upon which various and conflicting opinions prevail and it has been the cause of much dissatisfaction in particular quarters. The large majority of coroners, 240 out of 275, consider that the selection should be at the entire discretion of the coroner, and of the remainder, 22 are in favour of entrusting the post-mortem examination to an independent expert in all cases (although they do not state that the medical man concerned is not to be called upon to give evidence or to aid inquiry in other ways) and 13 are in favour of employing the medical attendant to perform the post-mortem examination. The suggestion contained in the memorandum that the coroner's inquest is not a suitable form of inquiry into deaths under anæsthesia, but that this should be carried out in private by a medical officer under the general control of the Home Office, is one of serious importance having regard to the number of cases in which a coroner's jury brought in a verdict of "misadventure" or "accidental death," details of which are given in Appendix IV. of the report. The memorandum of the London Council is lengthy and deals with many controversial matters which cannot be briefly commented on, but, together with other matters contained in the report not of such immediate medical interest, it will be reviewed in detail in a forthcoming issue of THE LANCET.

---

SIX Hunterian lectures on the Fossil Remains of Man and their Bearing on the Origin of Modern British Types will be delivered in the Theatre of the Royal College of Surgeons of England, in Lincoln's Inn Fields, by Dr. Arthur Keith, Conservator of the Museum, on dates already announced.[1] These lectures are designed to serve as an introduction to the study of the anthropological collection in the Museum of the College, and will be illustrated by means of the epidiascope. The subject will be considered under the following heads:—The fossil human remains found at Galley Hill, Kent; reconstruction of the remains; similar discoveries made at home and abroad; persistence of the type; the Heidelberg mandible; the extent to which a reconstruction of the individual may be effected; pithecanthropus; its discovery, nature, and relationships to human races; the Gibraltar skull; its discovery and bearing on the evolution of man; the Neanderthal race; recent discoveries in France; the bearing of acromegaly on the characters of this race; Huxley's "river-bed" type of ancient Briton; recent and old discoveries of this type; the relationship of the type to ancient and modern forms of Britons; recent discoveries of ancient human remains in Kent, Essex, and Herts; summary of the geological evidence relating to the origin of modern types of man.

---

IT is announced that their Royal Highnesses the Prince of Wales and Prince Albert are suffering from measles of a mild form. On the outbreak of the epidemic at the Royal Naval College, Dartmouth, they were isolated in the Commandant's house, and it was hoped that they would escape. They have not done so, but the Princes are at the age of least danger, and the important measure of confinement to bed, to the neglect of which so many complications and sequelæ are frequently due, is being enforced. It is to the complications and sequelæ of the disease, rather than to the disease itself, that the danger principally attaches, and these are very largely to be avoided by a proper appreciation of the risks.

[1] THE LANCET, Jan. 21st, 1911, p. 182.

---

THE lectures of the Royal College of Physicians of London for the present year will be delivered at the College, Pall Mall East, on the following Tuesdays and Thursdays, at 5 o'clock. Milroy lectures on March 2nd, 7th, and 9th, by Dr. A. E. Boycott, on Ankylostoma Infection; Goulstonian lectures on March 14th, 16th, and 21st, by Dr. A. F. Hertz, on the Sensibility of the Alimentary Canal in Health and Disease; Lumleian lectures on March 23rd, 28th, and 30th, by Dr. J. Mitchell Bruce, on a Clinical Study of Cardio-vascular Degeneration; Oliver-Sharpey lectures on April 4th and 6th, by Dr. J. Mackenzie, on Heart Failure.

---

THE report on the work of the Central Midwives Board for the year ended March 31st, 1910, has been printed as a Parliamentary Paper.

---

THE anniversary dinner of the Medical Society of London will take place at the Whitehall Rooms, Hôtel Métropole, on Wednesday, March 8th, at 7.30 P.M.

## MEDICINE AND THE LAW.

*The Liabilities of the Education Authority.*

THE burden of responsibility cast upon county councils by their position as the authorities charged with the elementary education of children does not diminish. Children are admittedly liable to injure themselves by accidents from which the most meticulously careful parents, guardians, and teachers are unable to protect them. If a pupil falls and hurts himself in a school playground the school authorities are likely to find themselves mulcted in damages because the accident was directly caused by some obstruction which they might have removed and over which the child tripped, and various accidents of this character frequently expose them to litigation. In a recent case the question of the council's liability arose thus. A vehicle was provided by the Herefordshire county council under powers given to it by the Education Act, in order that children living more than three miles from a certain school might be conveyed to it. A little girl called Shrimpton, not living at such a distance as would entitle her to ride to and from school but well within it, was allowed by the driver of the vehicle, presumably out of pure good nature, to get in and out because it passed her home. One day when she was alighting the vehicle moved on suddenly and she fell upon her head in the road, sustaining injuries for which a jury awarded her £277 against the county council. The council maintained that the person liable, if any, was the jobmistress from whom they hired the vehicle. In the Court of Appeal Lord Justice Fletcher Moulton and Lord Justice Buckley were of the opinion that the evidence at the trial showed no duty on the part of the defendant council of which there had been any breach or neglect, and reversed the judgment of Mr. Justice Channell in the court below, Lord Justice Vaughan Williams dissenting from their view. On appeal to the House of Lords the Lord Chancellor, Lords Halsbury, Ashbourne, Atkinson, and Shaw were unanimously of opinion that the Court of Appeal was wrong and restored the judgment for £277 damages. In giving judgment the Lord Chancellor said that the county council were not under a statutory obligation to convey the child in question to or from the school, but as they did, in fact, convey her they undertook the duty, as they did towards the other children, of providing a proper vehicle and of taking reasonable care of her. The jury had found that the accident had been caused by negligence; the council did not see that proper care was taken and the appeal must be allowed.

# MEDICAL INSPECTION AND TREATMENT OF LONDON SCHOOL CHILDREN.

*Medical Aspects of the Education Estimates.*

THE Education Committee of the London County Council on Feb. 8th had before it the annual estimates of expenditure for 1911–12. The total was £4,981,110, about half of which represented salaries of teachers. The following individual items may be mentioned: meals for underfed children, £89,545; medical inspection and treatment, £39,960; cleansing children, £2205; open-air schools, £1750; special schools—blind, £9915; deaf, £17,415; mentally defective, £56,950; physically defective, £42,480; epileptic, £2440—total, £129,200. Under the head of provisional sums for expenditure not yet sanctioned by the Council were the following items: further provision for dental treatment, £5000; provision for improving the working of the Council's arrangements with the hospitals, £1000; cleansing of verminous children, £2370. On the receipts side of the maintenance estimates were these entries: cost of meals recovered from parents, £905; ditto medical treatment, £550. The general purposes subcommittee, in its observations, said the estimated increase of £26,400 in the cost of school meals was due to the increased cost in the preparation and service of the meals consequent on the decision of the Council to appoint a number of supervisors. The increase of £20,885 under "medical inspection and treatment" was accounted for by the employment of additional school medical officers, and the treatment of children for eye, ear, and skin ailments. The estimate included a proportion of establishment charges not previously made, so that the actual increase was £12,000, of which £4000 represented the salaries of the increased medical staff. The estimate was based on provision for the treatment of 62,000 eye, ear, nose, and throat cases, and 1200 ringworm cases. The hospitals and medical treatment centres at present included in the Council's scheme could provide treatment for some 32,000 eye, ear, nose, and throat cases, and 1325 ringworm cases. The average cost was 4*s*. 6*d*. a case in respect of eye, ear, nose and throat ailments, and 17*s*. 10*d*. for ringworm cases. Of the provisional items of £5000 for dental treatment the subcommittee said that this was included to provide for "further experimental dental surgeries. This sum will also allow of general provision being made for a small portion of the year for all cases of London children requiring treatment." As to the improvement of the working of the Council's arrangements with hospitals the subcommittee said that at present it was not possible to obtain early information from the hospitals as to the attendance of the children, and many ceased attendance before treatment was completed. It was desirable, therefore, to make provision at the hospitals and medical treatment centres for following up cases, and so avoiding leakage. Regarding the recovery of the cost of treatment it was impossible to give any reliable estimate. From January to December, 1910, £185 were actually recovered from parents, but the children's care subcommittee was considerably in arrear with the assessment of charges. On Feb. 14th the Council approved a supplemental estimate of £23,800 in respect of feeding necessitous children, bringing the allowance under this head to £88,092 for the current financial year.

*New Medical Appointment.*

The Special Schools Subcommittee has presented a report in favour of placing the medical officer (education) formally in charge of the medical arrangements at the Council's special schools of all kinds, the local medical officers being instructed to communicate with him in all serious cases of illness and on medical matters affecting the schools. There was no reason why the scheme of sight-testing in force in ordinary schools should not be applied to schools for the deaf and physically defective, especially in view of the need those two classes had of preserving their eyesight if they were to become self-supporting, and the subcommittee was of opinion that this should be done. Owing to their unreliability under test it would not be desirable to apply the scheme to schools for mentally defective. The question arose of the additional medical staff necessary to carry out the work. The subcommittee calculated that it would be necessary to appoint additional staff to the extent of 189 sessions per annum (nearly one and a half quarter-time medical officers). The Council on Nov. 1st, 1910, has decided that there should be more detailed and frequent examination of children in special schools, and sanctioned the appointment of two additional quarter-time doctors for the work, but as this was the minimum staff required to carry out the wishes of the Council, no part of it could be employed to examine cases for admission. For supervision of medical matters in special schools an additional quarter-time assistant medical officer would be required, but rather than appoint the equivalent of two and a half quarter-time officers the subcommittee thought it would be better to abolish one of the present quarter-time posts and appoint a full-time officer as medical examiner under the Elementary Education (Defective and Epileptic Children) Act, 1899. This post would be of a grade somewhat lower than that of full-time assistant medical officer, but higher than that of a school doctor, and a suitable man could be obtained for a salary of £400 a year, rising by annual increments of £25 to a maximum of £500 a year. The proposal was approved except that "medical officer" was substituted for "medical examiner."

*Difficulties Arising out of the Medical Treatment Scheme.*

The Children's Care Subcommittee, in a long report, dealt with the whole question of the charges to parents in respect of the medical treatment of their children. The experience of the past year, it was stated, showed the scale by which remissions were calculated to be too complicated. (This scale took a "standard family" as consisting of two adults and four children, and went into such detail as to grant remissions varying by a penny or two as between a man having 22*s*. 6*d*. and one having 25*s*. per week.) The administration of this scale had been "a source of considerable difficulty." It had also to be stated that as prior to the arrangements made by the Council necessitous parents were able to obtain free treatment at most of the hospitals, many of them regarded the Council's arrangements as an interference with what they considered to be their rights and privileges. At the present time the work of assessing charges was seriously in arrear—out of 14,000 cases treated only 7000 had been assessed. Care committees objected to having to go through the trouble of assessing and presenting claims to parents where there was no intention to recover. Some care committees had declined to undertake the work at all. From the point of view of the hospitals it was contended that the fact that the Council made a charge to parents was likely to have a prejudicial effect upon subscriptions. Many subscribers contributed to the funds of a hospital because they were desirous of assisting poor people to obtain treatment. Many hospitals were constituted as institutions to provide "free treatment for the sick poor," and this had prevented certain of them from coming within the Council's scheme, and was understood to be the chief consideration which influenced the authorities of St. George's Hospital to withdraw from the scheme. Another difficulty arose in connexion with the Hospital Saturday Fund, 75 per cent. of which was obtained as the result of small sums contributed by employees in workshops and factories. Since the adoption of the Council's scheme certain of the hospitals—a relatively small number—had declined to accept in some instances Hospital Saturday Fund letters from children and had required a Council voucher instead. The supply of this voucher involved a charge to the parents by the Council. Parents who were subscribers to the fund considered that they made two contributions for the treatment received under the arrangements made by the Council.

Having regard to these considerations, the subcommittee thought the existing arrangements in respect of charges for medical treatment should be discontinued. It was not prepared to substitute a classification suggested by the Finance Committee on the following lines: (1) parents able to do so to pay the full amount; (2) parents able to pay only part of the cost, to pay a definite fixed amount; and (3) parents unable to pay anything to be exempted. This scale to apply to dental treatment, 1*s*. being charged where parents were only able to pay part of the cost. Such a system would not obviate detailed inquiries into the circumstances of parents or lessen to any appreciable extent the work of the care committees or obviate the other difficulties to which attention had been drawn. The subcommittee proposed that a uniform charge of 1*s*. should be adopted for the complete treatment

both of medical and dental cases, no charge to be made in necessitous cases or in cases where after careful inquiry it was ascertained that the parent had been accustomed to subscribe to the Hospital Saturday Fund or had any other legitimate claim to free hospital treatment.

The recommendations were approved, but a proposal to remit all existing arrears in order to relieve the care committees of the work of assessment was withdrawn by the chairman of the subcommittee.

*Open-air Schools and Playground Classes.*

The committee decided, subject to the approval of the Board of Education, to continue the open-air schools held in London for the last three years and also the playground classes begun last year. The Day Schools Subcommittee stated that the reports on the playground classes were extremely favourable. The medical officer (education), Dr. Kerr, dealing with a class at Bethnal Green said the children selected were representative of the lowest stratum in that part of London. Without necessarily presenting signs of organic disease they were ill-nourished, ill-clad, pallid, and inert. The very first medical examination three weeks after the inception of the class left no doubt as to the highly beneficial effect of the régime out of doors upon the children. The school doctor, said Dr. Kerr, stated that in many cases he felt doubtful for a moment whether the children were the ones he originally selected, the difference was so great. Instead of a habitual condition of apathy and dulness the children displayed an interest in their work and a readiness to respond. Their demeanour was unmistakably more alert and spirited. The health of the children in no case suffered, while colds were almost entirely absent. The subcommittee mentioned, in regard to open-air schools, that the report upon last year's working was not yet ready, but there was no doubt it would be similar to those presented in 1909 and 1908. There were two hindrances to their extension—it had been found impossible to secure suitable sites in those parts of London where they were most needed, and the administration was costly, the average per head being about £20 per annum.

# ANNUAL REPORT FOR 1909 OF THE MEDICAL OFFICER OF HEALTH OF THE ADMINISTRATIVE COUNTY OF LONDON.

## III.[1]

*Diphtheria.—Enteric Fever.*

AMONG the diseases the spread of which is believed to have relation to the aggregation of children in schools, a prominent place in these reports is always accorded to diphtheria. In the year under notice the proportion of reported cases of this disease (including membranous croup) was the same as it had been in 1905—namely, 1·4 per 1000 of the population at all ages, which is the lowest rate hitherto recorded in London. The disease, however, appears to have assumed a somewhat more fatal type, for the case-mortality among the reported cases was above the average in the four years immediately preceding More than four-fifths of the cases known to the sanitary authorities are now treated in the hospitals of the Metropolitan Asylums Board; and we are concerned to note that among the cases medically certified to be diphtheritic, and admitted as such to the wards, the proportion of instances of mistaken diagnosis in the year under notice was as high as 16·8 per cent. In three of the metropolitan boroughs—viz., Lambeth, Greenwich, and Stoke Newington—the medical officers of health are supplied with antitoxic serum for use by medical practitioners. The experience of the Metropolitan Asylums Board, gained in the Board's hospitals, is emphatic as to the importance of making antitoxic serum available for use without delay. Among hospital cases treated with this serum in 1908 the mortality is reported to have been as follows: In cases where the treatment was begun on the first day of illness, 3·0 per cent.; on the second day of illness, 6·5 per cent.; on the third day, 10·6 per cent.; on the fourth day, 12·9 per cent.; and on the fifth day and later, 14·8 per cent. The metropolitan boroughs showing the lowest proportions of attack by diphtheria were Hampstead, where the rate was equal to 0·50 per 1000 living, and Stoke Newington, where it was 0·52 per 1000. The boroughs with the highest rates were Woolwich, 2·01 per 1000, and Lewisham, 2·42 per 1000.

Enteric fever was less prevalent than usual in 1909. The distribution of the disease in London was exceptional, the usual autumnal rise being absent. The rate of attack by enteric fever was the lowest on record, and so likewise was the rate of mortality. In many who were medically certified to be suffering from enteric fever the diagnosis was not subsequently confirmed. Among the several sanitary areas the attack rate of enteric fever was highest (0·45 per 1000) in Shoreditch; it was lowest (0·09 per 1000) in Woolwich, and 0·11 per 1000 in Lewisham. In proportion to the living the attacks were most numerous in both sexes at ages from 10 to 15, whilst the death-rate was highest at ages 25 to 35 among males, and at ages 15 to 20 and 25 to 35 among females.

*Pulmonary Tuberculosis.*

To the behaviour of pulmonary tuberculosis in London considerable prominence is given in the present report. A new as well as an instructive diagram is presented showing the corrected rate of mortality from tuberculous phthisis in relation to the mean rate of the period 1851–1909. The diagram shows a marked decline of phthisis mortality in both sexes, and a greater incidence of that mortality in the male sex. It further indicates that until the last seven years the decline has been more manifest in females than in males. Sir Shirley Murphy is, however, careful to point out that this alteration in the relative decline in the death-rate of the sexes in recent years may be apparent only, inasmuch as it would be explicable in the event of the relative proportion of the sexes having changed since the last Census. The tendency to decrease in the mortality from phthisis has been general; among the metropolitan boroughs there are only three in which that mortality has not fallen since the five-year period 1904–08.

In an interesting table the mortality from phthisis in groups of districts is shown in relation to overcrowding as a measure of social condition. From this table it appears that if the phthisis mortality of the whole of London be represented by 1000, the mortality of the districts where overcrowding does not exceed 7·5 per cent. is represented by 709, whilst that of the districts where the overcrowding amounts to 27·5 per cent. the comparative mortality figure is 1394. Equally conspicuous is the close relationship between social condition and phthisis mortality, as indicated by similar tables in the reports of recent previous years. In the group of most overcrowded districts the phthisis mortality is, usually and approximately, twice that in the least overcrowded districts.

With the object of more fully illustrating the effect on phthisis mortality of social condition, as measured by the proportion of children scheduled for education purposes, a second diagram has been constructed in which the death-rates of both sexes at several age-groups are compared, after exclusion of the deaths in public institutions of persons whose last known residence was a common lodging-house. For the use of those who prefer the ordinary form of statistics a table has been prepared, from which it appears that the male phthisis death-rate is greatest at the age of 45, but that the female rate, whilst greatest at that age in the three most favoured district groups, is greatest at the age of 35 in the two least favoured groups; and this fact holds good whether the deaths among inmates of lodging-houses are, or are not, excluded. From this we see that, as between age 35 and age 45, the female rates of phthisis mortality show a tendency to greater incidence at the earlier ages as social conditions become less favourable. This tendency is not shown by the male rates. And here it deserves notice that the more general employment of servants in the better-class districts is a factor probably contributing to this result. In so far as young women suffering from phthisis would die, not at the houses in which they were employed, but in their own homes, this circumstance would tend to diminish the incidence of phthisis mortality in the more favoured, and to increase it in the less favoured districts.

*Phthisis Deaths in Workhouses and in Other Institutions.*

From figures quoted on the Registrar-General's authority we learn that almost half the deaths of males, and

[1] Previous notices of this report have appeared in THE LANCET of Jan. 14th (p. 110) and Feb. 4th (p. 322) and 11th (p. 393).

nearly one-third of the deaths of females, occurred in workhouses. The intimate association of phthisis with poverty is strikingly shown by these figures; and from the same source it may be gathered that many more men than women die in workhouses, probably because destitution especially supervenes when the husband fails in health. If the districts are grouped on the basis of social condition of the inhabitants, practically identical proportions will be observed. Thus it appears, from a further table, that whilst in the most favoured districts 39·8 per cent. of the males die from phthisis in workhouses, in the least favoured districts the percentage is 52·5. On the other hand, the female deaths in workhouses in the best and the worst districts differ by less than 3 per cent.

*Administrative Control of Pulmonary Tuberculosis.*

As regards the administrative action taken in London for the suppression of pulmonary tuberculosis, very full particulars are given in this report. The county medical officer of health, with the help of his staff, has made careful inquiry concerning the preventive measures taken in each metropolitan sanitary area respecting cases of this disease coming to the knowledge of the sanitary authorities. At the present time voluntary notification of pulmonary tuberculosis obtains in most of the sanitary districts, and this system has been recently supplemented by an Order of the Local Government Board requiring the notification to the medical officer of health of all cases of this disease occurring in Poor-law practice, and empowering local authorities to adopt measures for the prevention thereof. This Order provides for pulmonary tuberculosis to be dealt with as an infectious disease, and this view, together with the steps necessary for the suppression of the disease, is set forth in a Memorandum by the Board's medical officer. The Order in question enables a sanitary authority to exercise wide powers in aid of the most necessitous class of the community. It would appear to authorise the provision of hospital and sanatorium accommodation for cases of phthisis, and in suitable cases to ensure that a separate sleeping room should be provided for the patient. The result of the Tuberculosis Order has already been that the number of cases notified has been more than doubled, but even this number must, of course, fall short of the total actually occurring. "It may therefore be considered," says Sir Shirley Murphy, in a weighty sentence, "whether obligatory notification of patients in all classes of the population would produce very different results." In a few provincial towns voluntary notification has been followed by compulsory notification, and the local medical officers of health have communicated to Sir Shirley Murphy the results of their work. As a result of comparing the experiences of the officers referred to, it appears (*a*) that voluntary notification may fail to bring to the knowledge of the medical officer of health as many cases of pulmonary tuberculosis as there are deaths from this disease; (*b*) that when voluntary notification is supplemented by obligatory notification of cases occurring in Poor-law practice, the number of notifications is materially increased, but that it does not bring to knowledge more than a proportion of the clinically recognisable cases; and (*c*) that compulsory notification of phthisis, whether in Poor-law or other practice, brings to the knowledge of the medical officer of health a number of cases in excess of the number of deaths, but this number is still obviously less than the number of clinically recognisable cases. Appended to this report is a statement relating to each sanitary district, showing the steps that are taken locally, in the interest of the patient and of those with whom he is associated, on the medical officer receiving notice of the occurrence of a case of phthisis. In some few cases the house is visited by the medical officer of health personally, but usually by a sanitary inspector or health visitor, and advice is given on important points. In some districts, moreover, the services of a local health society are available. Adequate provision is apparently made in some cases for the supervision of the patient at home. In others the steps taken can hardly be described as satisfactory. Especially it should be noted that the steps taken do not include the medical examination of other members of the family. This is an important omission, for we know that the early detection of incipient cases and the provision of appropriate treatment for the patient are the most promising of the prophylactic measures that can be adopted.

In reviewing the facts at his disposal the county medical officer deliberately states the conviction that "at present it cannot be said that in London, as a whole, any material effort has been made to deal with this disease. Especially is effort wanting to detect early cases of phthisis, and to provide for their subsequent treatment. It needs to be noted that in Paddington, as the result of philanthropic effort, a dispensary has been instituted which is rendering useful service in these directions, and that in one or two other districts the provision of such an institution is being undertaken; but in the districts generally, little has been done to exercise the powers conferred by the Order of the Local Government Board."

*Milk-supply and Tuberculosis.*

In addition to the Dairies and Milkshops Order of 1899, which provides that the milk of cows certified by a veterinary surgeon to be suffering from tuberculosis of the udder shall not be sold or used for human food, the London County Council obtained powers in 1904 to remove from a dairy any cow suspected to be suffering from tuberculosis of the udder. Since that date the cows in the London cowsheds have been periodically examined by the Council's veterinary inspectors, and in this way 28 cows suffering from tuberculous diseases of the udder have been removed and slaughtered.

Under the General Powers Act of 1907 the Council officers are empowered to take for analysis samples of milk at the London railway termini consigned to dealers in London. In the year under notice 2325 samples of milk were taken by the Council's inspectors and conveyed to the Lister Institute for bacteriological examination. The result is that out of 1966 completed examinations of samples taken from churns consigned to London dealers 205, or 10·4 per cent., proved to be tuberculous. In the previous annual report it was stated that out of 528 examples examined in 1908, 11·6 per cent. were found to be tuberculous.

## ROYAL COLLEGE OF SURGEONS OF ENGLAND.

### THE HUNTERIAN FESTIVAL.

THE delivery of the biennial Hunterian Oration at the Royal College of Surgeons of England on Tuesday last, Feb. 14th, was followed in the evening by a banquet given by the President and Council of the College to a distinguished group of visitors, the principal guest being the Lord Mayor of London, Sir Thomas Vesey Strong, while among others present may be mentioned the Bishop of Bristol, Sir Herbert Maxwell, Mr. Walter Long, M.P., Lord Ilkeston, Lord Sandhurst, Lord Goschen, Sir Ernest Waterlow, Sir James Linton, Sir James Porter (Medical Director-General of the Navy), Surgeon-General Gubbins (Director-General of the Army Medical Service), Mr. Rider Haggard, Sir. E. Ray Lankester, Sir Alfred Cripps, and Sir Squire Bancroft.

After dinner and the Royal toasts, "The Memory of John Hunter" was drunk in silence, and immediately thereon the President, Mr. H. T. BUTLIN, proposed the health of the visitors, coupling the toast with the name of the Lord Mayor of London, and taking the opportunity to point out publicly that the Hunterian Museum in the custody of the College was in reality a State Museum. After alluding to the many distinguished guests who were present, the President said that it was some years since the College had entertained the Lord Mayor and Sheriffs, but they liked to do so from time to time in recognition of the hospitalities which were accorded by the City of London to the representative of the College, and also to remind the College of its origin in a City Corporation. When the surgeons separated from the barbers it was to form the Corporation of Surgeons, with its Master and Court of Assistants, and their dwelling-place was in the Old Bailey. He thought their City guests, particularly the masters of the City corporations who honoured the College with their presence, would like to know whether the College maintained the traditions of the corporations: in fact, how the College disposed of its revenues. The College rarely appeared in lists of donations or subscriptions. It had been suggested to him that the Council of the College spent money on themselves, and that he, the President, received an income of £5000

a year! He only wished it was so. But he was sorry to say that no salary was attached to the offices of President, Vice-President, or member of the Council. There were no pensions or sinecure offices, no almshouses for decayed Members of the Council, no schools for the education of their children. Even the hospitalities of the College were very limited: a dinner once a year at the most, sometimes only one dinner in two years. But the Council were going to show their guests to-night the way in which they spent their income. The museum had been specially lighted for the purpose. It had been in their possession for about 110 years, and it had been computed by those who compiled the guide-book for the British Medical Association last summer that it had cost the College more than £500,000. He could not say certainly if this were so because, although the accounts of the museum were separately kept, no charge had been made on it towards the secretarial department and general upkeep of the College. But he knew that the College had spent out of its own money more than £100,000 for buildings alone, and he thought the estimate was probably not exaggerated. It might be said that, after all, the museum was the property of the College, and it was not a matter of interest to the outside world whether it cost much or little. That was not the case. The museum did not belong to the College. It was a national museum, and he doubted whether there was any similar instance of a national museum being kept and paid for by a private body like the College of Surgeons. The history of the museum was that it had been collected in the course of 30 or more years by Mr. Hunter, who declared that he had spent £70,000 upon the 13,000 specimens of which it consisted. At his death, in 1793, it was the only property he left to his widow and her two children. It was offered to the nation, but Mr. Pitt was advised not to purchase it, as it was not of national interest. Six years later, just as it was on the point of being dispersed and sold bit by bit, Lord Auckland and some other distinguished persons persuaded the Government to buy it for £16,000. When they had done so Mr. Pitt did not know what to do with it, and offered it on trust to the Corporation of Surgeons. On their acceptance of the trust a sum of £15,000 was provided by the Government to house it. In the last 110 years the Government has furnished altogether just over £57,000 for assistance in building fresh accommodation. But the College has provided nearly twice as much for that object and has maintained and enlarged the museum entirely at its own expense. Yet it still remains a national museum, guarded by 31 Hunterian trustees, many of whom are trustees by virtue of their office, as the Lord Chancellor, the Prime Minister, the Speaker of the House of Commons, the Ministers of the Navy and the Army, and others. The trustees meet regularly every three months and visit the Museum when they will. The Council of the College is only represented among the trustees by the President. So strict are the regulations that we are not permitted to destroy or remove a single Hunterian specimen without the approval of the trustees. In spite of this, there is nothing connected with the College in which the Council takes greater pride, or on which it more willingly spends time and money than the Museum. It now consists of a vast number of specimens, and is undoubtedly by far the most splendid museum of its kind in the world. Only last year one collection of more than 5000 specimens was added to it by the Royal Society of Medicine (the Odontological Section). The President hoped their guests would be pleased to enjoy their cigars in the Museum, as His Majesty the late King had done on more than one occasion, adding that the Museum is largely used, for there are over 1000 attendances every month.

The LORD MAYOR, in his reply, confessed his pride, as the representative of the City of London, in the development of the old City Guild into a powerful and scientific corporation.

Lord ILKESTON proposed the health of the Hunterian orator, and Mr. EDMUND OWEN replied in a happy manner.

The company then finished a thoroughly interesting and entertaining evening in the Hunterian Museum, which was brilliantly lighted up for the occasion.

---

### MEETING OF COUNCIL.

AN ordinary meeting of the Council was held on Feb. 9th, Mr. BUTLIN, the President, being in the chair.

The PRESIDENT reported the death on Jan. 18th last at the age of 80 of Mr. Henry Power, past Vice-President and past member of the Council. It was resolved that—

> The Council do hereby record their deep regret at the death of Mr. Henry Power, who for 11 years was a member of the Council and devoted to the service of the College. He was highly esteemed, not only for his professional attainments, but for his personal qualities, which won for him the respect and affection of all who knew him.
>
> The Council also desires to express their very sincere sympathy with Mrs. Power and the members of his family in the loss which they have sustained.

It was resolved to issue Diplomas of Membership to 74 candidates found qualified.

It was resolved, on the recommendation of the Court of Examiners, that Clause 2, Subsection 2, and Clause 5, Subsection 3 of Section 3 of the regulations for the Diploma of Fellow should be altered so as to read—

> Dissections during the regular vacations will be accepted provided the certificate shows that they have been performed under the superintendence of an authorised teacher in a medical school.

It was resolved that jointly with the Royal College of Physicians Diplomas in Public Health should be granted to 21 successful candidates.

On the recommendation of the Committee of Management it was resolved:—

> That a Diploma in Diseases and Hygiene of the Tropics be granted by the Royal Colleges after an examination conducted under the superintendence of the Conjoint Board, and that one Examiner in Bacteriology and one Examiner in the Diseases and Hygiene of the Tropics including Surgery be appointed by each of the Royal Colleges.

A syllabus of the subjects of the examination has been drawn up and was approved.

Mr. C. H. Golding-Bird was reappointed as the Representative of the College on the Central Midwives Board.

The PRESIDENT reported the delivery of Hunterian Lectures by Dr. F. W. Edridge-Green on Colour Vision and Colour Blindness, and by Dr. W. d'Este Emery on the Immunity Reaction in Diagnosis, especially in Tuberculosis and Syphilis.

The PRESIDENT reported that in pursuance of the provisions of the Bradshaw Bequest he had chosen Mr. R. Clement Lucas as Bradshaw Lecturer for the ensuing collegiate year.

A letter was read from the Secretary of the Royal Society of Medicine stating that at the last meeting of the Council of this society it was unanimously resolved to present to the Royal College of Surgeons the Osteological Collection formerly belonging to the Obstetrical Society and at present stored in the basement of the College.—The best thanks of the Council were given to the Royal Society of Medicine.

---

## THE HEALTH OF THE NAVY IN 1909.

THE Statistical Report on the Health of the Royal Navy for 1909, issued late last year, and noticed briefly in THE LANCET on Feb. 4th, merits detailed notice. The report continues to show a general improvement in the health of the premier service. It deals with a total force of 112,700, a large majority of whom—viz., 76,330—were serving at home. In March, 1909, the command previously known as the Channel Fleet was absorbed into the Home Fleet. This amalgamation brings back the number of separate commands to ten, as was the case previous to 1908, when the Home Station was split up into Home Station and Home Fleet.

*Statistics.*

In all statistical respects the health returns are satisfactory, the ratios of cases of sickness and injury admitted, for invaliding, for mortality, and for average loss of service, being all lower than the average of the previous five years. The total number of cases of disease and injury that occurred was 72,540; this gives a ratio of 643·65 per 1000, showing a decrease of 75·34 on the quinquennial average. The average sick-rate was 26·75 per 1000, being 2·84 per 1000 less than during the preceding quinquennium. The average loss of service was 9·76 days for each person, or 1·04 less than the five-year average. The highest ratio of men sick daily occurred, as usual, in the Irregular List, among the crews of vessels on passage to or from foreign stations, or employed on the west coast of North America, amounting to 45·76 per 1000; next to this comes the Home Station, with 35·42 per 1000; China and the East Indies were also slightly above the mean, but all the other commands were below the mean, the healthiest being Cape of

Good Hope, with 20·14. It is to be noted that the men of the Home Fleet had only 23·19 per 1000 sick every day on an average, being much healthier than those of the Home Station, which consists of depôt and training ships, the home hospitals, and the Royal Naval College at Greenwich. The deaths in the whole navy numbered 362, or 3·21 per 1000, and the invalidings 1764, or 15·65 per 1000; the ratios for the preceding quinquennium were 3·75 and 16·51 respectively.

Taking the statistics of the navy as a whole, and examining into the relative importance of the different causes of inefficiency through sickness we may compare the admissions and the number daily sick under each heading, as stated in ratios per 1000 of strength. For all causes the admission ratio was 643·65 and the number sick every day 26·75; of these, venereal affections accounted for 119 admissions and 7·9 constantly sick; the group of digestive diseases caused 103 admissions per 1000 and 2·9 constantly sick; diseases of the skin and connective tissue come next with 73 and 2 per 1000; and then respiratory diseases with 69 and 1·6 per 1000 ratios. Influenza is always prevalent in the navy and, though less so this year than has been the case recently, accounted for 20 per 1000 admissions to hospital. Local injuries are also an important cause of admission, amounting to 131 per 1000, the average number constantly sick being 4·36 per 1000, a higher ratio than for any other single disability. But in all these instances (except the first named) the number of individual cases and the total amount of sickness, as shown by the average ratio per 1000 daily sick, were less than in the preceding quinquennium. With regard to venereal diseases taken as a whole, there was no improvement; the admissions per 1000 were 119·5, compared with 120 in the five years preceding, and the average sick-rate was 7·9, compared with 8·2; there does not seem to have been any diminution in the severity of the affections, nor acceleration of recovery by the improved methods of treatment adopted. The total disability from this cause amounted to an average of 892 men in hospital every day throughout the year. The most fatal of the causes of disease was, as in the previous year, pneumonia (37 deaths, 0·32 per 1000); enteric fever caused 28 deaths (0·24 per 1000), and tuberculosis 22 deaths (0·19 per 1000). The chief causes of invaliding were tuberculosis (209 cases, 1·85 per 1000), nervous diseases (also 209 cases, 1·85 per 1000), heart disease (149 cases, 1·32 per 1000), and diseases of the digestive system (274 cases, 2·43 per 1000), defective teeth and hernia (operation refused) being the principal items in this last category; only 23 cases of hernia, however, were invalided, while 519 were operated on for radical cure with excellent results in all but three or four instances.

A comparison of the statistics of the different commands shows that the East Indies Station suffered most, having a case-rate of 959, a death-rate of 9·04, and 25·53 per 1000 invalided; 5 out of the total of 17 deaths were due to beriberi. Malaria admissions were at the rate of 145 per 1000, while pyrexia caused 97 per 1000; the other chief causes of sickness were affections of the digestive system and of the connective tissue and skin. The healthiest commands were the Home Fleet (560 per 1000 admissions and 2·73 deaths), and that of the Cape with 570 admissions per 1000 and no death.

### *Prevalence of Chief Diseases.*

The most important diseases may now be shortly considered in regard to their prevalence and distribution. The admissions for *influenza* numbered 2280, of which 4 were fatal; cases occurred in all the commands; as it led to no necessity for invaliding men out of the service it was nowhere of a severe type; three of the deaths were due to pneumonia, and one to heart failure, all occurring at home. 35 cases of *diphtheria* occurred, 22 being on the Home Station, and 10 of these on the *Impregnable* training-ship for boys. In the Home Fleet cases of acute infectious disease, such as measles, scarlet fever, mumps, &c., were frequently introduced into crowded ships; but there was rarely any spread of the disease, which speaks well for the promptitude of recognition and adequacy of preventive measures.

*Enteric fever* caused 150 admissions and 28 deaths; 31 of the cases were admitted on the Home Station, most being thought to have contracted infection while on leave, or staying at their homes. In only one case is a cause suggested, the eating of cockles. 46 cases occurred in the Home Fleet, in regard to 3 of which it was "almost conclusively proved that shellfish were the cause"; and 4 cases in other ships were ascribed to the same source of infection; at Queenstown two officers partook of oysters and developed enteric, one case being fatal. One case on the *Prince of Wales* in the Atlantic Fleet is said to have been due to eating cockles at Portsmouth. On the Mediterranean station 30 cases occurred; in the outbreak on the *Swiftsure* there were 12 cases, to which number should be added 9 further cases occurring in 1910; the movements of the men are carefully detailed in the report, and the conclusion is reached that probably infection was due to contaminated food at Suda Bay and Phalerum or the Piræus, though contact infection could hardly be excluded. Shore infection at Bermuda is thought to have been the cause of 5 cases on the North American station; it is also suggested that the germs might have been carried by flies, which existed in swarms at the time. On the irregular list 7 cases are recorded, 2 of which appear to have been infected at Hong-Kong; 2 others occurred shortly after leaving England for Australia, one of whom had eaten oysters at Portsmouth a fortnight previously. *Pyrexia* of uncertain origin caused numerous admissions in the Mediterranean, most being trivial cases; a series of 12 on the *Bacchante*, with an average duration of 18 days, of slight severity and favourable termination, are attributed to infection at the Piræus, and were probably cases of phlebotomus fever due to sandfly infection. On the China station a few cases occurred of the so-called "Yangtse river fever," which are returned under this heading. In the appendix is given a clinical description of the cases. The pyrexia is of an intermittent type, reaching 102° to 103°, lasting some 10 to 14 days, and accompanied by an urticarial rash; sometimes also there may be dyspnœa, dysphagia, or diarrhœa. It is thought that the urticaria "may affect any part of the body inside or out." The disease seems to be infective and to be in some way connected with freshly turned soil.

*Pneumonia* was an important cause of sickness, accounting for 4·18 admissions per 1000 of strength. This shows a slight decrease on the average for the preceding five years, but on the home station there was an actual increase, the ratio being 8·31 per 1000, compared with the previous average of 6·23. The cases numbered 218 and there were 17 deaths; 48 cases were admitted on the *Vivid* (general depôt ship). It is stated that the disease "could not be traced to any insanitary condition, and was most prevalent in the early summer." Pneumonia was also the most fatal disease, 37 deaths being due to this cause, giving a ratio of 0·32 per 1000.

*Malaria* was somewhat more prevalent in 1909, the case-rate being 5·42 per 1000, compared with a ratio of 5·09 for the quinquennium. On the East Indies Station the case ratio was 145·21 per 1000, a considerable increase on the quinquennial average of 118·47, though much less than the admission rate in 1908, which was 252·9. The majority (135) of the cases this year, as last, were admitted on the *Perseus*, lying in the dockyard, Bombay; in 1908 the men lived at the Sailors' Home in Bombay; this year nearly all the seamen ratings and marines went up to Deolali; the engineer and stoker ratings and a few seamen, signalmen, and marines lived in the Sailors' Home, Bombay. At Deolali it was quite healthy—very few mosquitoes and very little fever. At Bombay the men worked on board in the dockyard from 8 till 2 all through the rainy season. Every man had a mosquito net and was made to use it, and 10 grains of quinine were given to each thrice weekly. The mosquitoes swarmed on board, and bit as much in the day as at night. Citronella oil, smeared on exposed parts, kept off their attacks to some extent. The type of fever was not so severe as in 1908.

*Tuberculosis* caused 320 admissions, and was the most important cause for invaliding, 209 men having to leave the service on this account; both case and invaliding ratios, however, are lower than the quinquennial average, and the death-rate (0·19 per 1000) is only half that of the preceding five-year period (0·38). The case ratio for the whole navy was 2·83 per 1000; for ships' stewards it was 12·9; for sick-berth staff, 8 84; and for cooks, 8 61; for seaman ratings it was 2 46.

The *venereal* statistics, as already mentioned, show little improvement, but it is to be noted that "the system which

now obtains of invaliding cooks and domestics and similar ratings who are rendered entirely unfit for the performance of their duties by the presence of venereal disease, if they are unlikely to recover completely within a reasonable period, tends to increase the number of cases invalided." The case and invaliding ratios were 119·53 and 1·35 per 1000 respectively.

*Rheumatic fever* shows a serious increase, there having been an admission ratio of 7·22 per 1000, more than double that of the preceding five-year period, which was 3·46; it is also an increase over the admissions in 1908, which were 6·51 per 1000, and a great advance on the average for the five years 1903–07, which was only 2·68 per 1000. The increase has been notable in all commands except the Australian, and in the Home Station and in the Home Fleet. The report states that "as in 1908, the case ratio shows a decided increase (3·76), which is possibly in part dependent on the concentration of the fleet in the cold and stormy home waters, but to some extent is perhaps due to more careful classification" (p. 7). The admission ratio has been more than doubled; the term "decided" is not adequate to express an increase of 108 per cent. (or if the five years, 1903–07 be compared, of 169 per cent.); it is conceivably partly to be explained by the concentration suggested; but *all* the stations except the Australian show a similar increased prevalence. (Later on we find a reduction under diseases of the organs of locomotion from a quinquennial average of 22·13 to 13·58 per 1000; "joint inflammation" is probably, therefore, now more correctly returned as rheumatic fever.) Whatever was comprehended under this heading, the mortality ratio was low, only 3 cases having been fatal out of 814.

Only 115 cases of *alcoholism* occurred in the whole force of 112,700 men; Dr. Tobias Smollett would have wondered. There were four deaths, one due to gastro-enteritis, "the patient being entirely unaccustomed to alcohol."

Of *poisoning* there were 111 cases, more than half being due to ptomaines (57); most of these came from eating tinned provisions, such as tinned fish. There were 22 cases of "beri-beri," all occurring amongst native ratings (lascars) in the Persian Gulf Division of the East Indies Station. Staff-Surgeon A. J. Laurie gives a careful account of the outbreak in a special paper in the appendix to this report. He states that the rice was undoubtedly good and well cured, but that the copper cooking vessels were not properly tinned; indeed, they were not tinned at all for eight or ten months; he considers, therefore, that the "beri-beri" was due to copper poisoning, not to any faulty condition of the rice. Purulent gingivitis was present in 8 out of 11 cases specially observed, and the pus in some instances gave the reaction of copper. There is, however, no detailed clinical description of the symptoms, and a doubt arises as to the real nature of the disease.

Of the *local diseases*, those of the nervous system show a reduction in point of number, the cases having been 6·92 per 1000, compared with the quinquennial average of 8·38.[1] Circulatory diseases caused a larger number of deaths than any other group, except pneumonia, but were not more severe or numerous than usual. Respiratory diseases were numerous, but not fatal; and diseases of the digestive system furnished far more admissions to hospital than any other group (except venereal), showing, however, some decrease on the quinquennial average. Sore-throat and tonsillitis are included under this heading, though often independent of any condition connected with digestion. No outbreaks, however, are recorded attributable to any insanitary conditions. We are not able to gather from the figures presented what are the present dental conditions in the Royal Navy, how they compare with those in young adults in civil life, or whether they are improving, or the reverse. With the increased care that is now being taken of the teeth in school children there should soon result an improvement in the dental conditions of young adults in the public services. There is a large reduction in the admissions for diseases of the connective tissue and skin, which now stand at 73·36 per 1000, compared with 101·36 for the five years 1904–08. It is considered that the withdrawal of so many men from tropical service during late years has largely accounted for this; in the East Indies Command the ratio is still 153 and in China 119·9; while both in the Home Station and in the Home Fleet it is only 60. General *injuries* are slightly below the average (2·52 as compared with 2·63 per 1000). There were actually 285 cases with 80 deaths. The unfortunate sinking of Submarine "C 11," with a loss of 13, and the running down of the pinnace of the *Encounter* in Sydney Harbour, with a loss of 15, were the most important accidents that occurred during the year.

[1] A misprint in the figure for invaliding ratio on p. 95 has unfortunately led to an error in the text of the report on p. 8, where 2·17 should be read instead of 3·17.

*Appendix.*

In the appendix notes are furnished of five cases of *caisson illness* during the year 1909, which are interesting and of practical value to naval officers. A little more care might have been given by the editor. In the account of Case 2 it is said that the patient had a sub-normal temperature "until July 25th"; but as the date of the occurrence is not mentioned this gives no real information. Fleet-Surgeon W. W. Pryn contributes an admirably clear and interesting exposition of the various methods of *colour vision testing*, with especial reference to that employed at the Admiralty; he sums up that (1) an examiner should himself have normal colour vision; (2) as required for sea service it is best tested by means of a lamp; (3) of these the Edridge-Green is the best form; (4) the practice of requiring the coloured lights to be matched with wools is to be recommended; (5) the Holmgren test is useful as an auxiliary. Another useful paper is that of Fleet-Surgeon A. G. Wildey on the Vision of Men under Training at the Gunnery School. Of 676 examined, 15·82 per cent. were found to be defective, chiefly owing to astigmatism; but the ametropic errors were small. He believes, however, that inability to read Snellen's types at normal distances, unless it be due to organic disease, does not materially affect the accuracy of shooting in the gunlayers. He very reasonably points out that it is no detriment to men of the stoker class, who have to read gauge-glasses, engine-room thermometers, &c., to be unable to read the types at six metres; among the older men of these ratings the slightly myopic have indeed the advantage. In a report on the eyesight-testing of gunlayers and others at Whale Island, Fleet-Surgeon W. A. Whitelegge notes that astigmatism is relatively common. Out of 83 cases of visual defect 32 were due to this cause; the men, however, were able to correct the errors by very slight adjustment of the telescope, and made excellent shooting at the battery. He has no doubt that eye-strain in the service is increasing, owing to the powerful telescopes now in use, and the glare of the sea. Staff-Surgeon Oswald Rees, whose very interesting observations on body temperature and the cause of heat-stroke appeared in last year's report, returns to the subject in the present issue. Fleet-Surgeon F. H. A. Clayton and Staff-Surgeon C. H. J. Robinson also contribute notes of the cases of cramp due to high temperature in the China Seas. We heartily welcome these contributions to professional literature in the Naval Medical Report, which we are glad to see is much fuller (nearly 90 more pages) than last year. The fuller notes this year on the causation of disease in the various commands are also very welcome; but, like Oliver, we ask for more: more extended accounts of professional work, preventive and curative, under the great variety of conditions in which the Royal Navy serves in all parts of the world.

## VITAL STATISTICS.

### HEALTH OF ENGLISH TOWNS.

IN 77 of the largest English towns 7890 births and 5255 deaths were registered during the week ending Feb. 4th. The annual rate of mortality in these towns, which had been equal to 15·5, 16·4, and 16·1 per 1000 in the three preceding weeks, declined to 16·0 in the week under notice. During the first five weeks of the current quarter the recorded death-rate in these towns averaged 15·7 per 1000. In London the mean death-rate during the same period was equal to 15·8 per 1000. The annual death-rates in the 77 towns during the week ranged from 5·1 in Hornsey, 8·7 in Wolverhampton, 9·0 in Aston Manor, and 9·1 in Handsworth (Staffs), to 21·6 in Oldham, 23·5 in Middlesbrough, 24·1 in Swansea, and 24·5 in Bury. The 5255 deaths from all causes in the 77 towns in the week under notice showed a decline of 56 from the number returned in the previous week, and included 477 which were referred to the principal epidemic diseases, against 448, 455, and 461 in the three preceding weeks; of these 477 deaths from epidemic

diseases, 230 resulted from measles, 116 from whooping-cough, 52 from diphtheria, 47 (of infants under two years of age) from diarrhœa, 21 from scarlet fever, and 11 from enteric fever, but not one from small-pox. The fatal cases of measles, which had increased in the four preceding weeks from 160 to 208, further rose to 230, and caused the highest annual rates of 1·9 in Tottenham, in West Ham, in Coventry, and in Stockton-on-Tees, 3·5 in Grimsby and in Sheffield, and 5·4 in Rotherham. The deaths attributed to whooping-cough, which had been 87, 85, and 113 in the three preceding weeks, rose again to 116; the highest rates from this disease were 2·3 in Rotherham, 3·3 in Norwich, and 3·6 in Willesden. The 52 deaths from diphtheria showed an increase of 4 upon the number in the previous week, and included 12 in London, 7 in Leeds, 4 in Birmingham, 4 in Liverpool, and 3 in Salford. The deaths of infants under two years of age attributed to diarrhœa and enteritis, which had been 68 and 58 in the two preceding weeks, further declined to 47. The fatal cases of scarlet fever, which had declined from 31 to 17 in the three previous weeks, rose to 21; 6 deaths occurred in London, 3 in Birmingham, and 2 each in Leyton and in Liverpool. The 11 deaths referred to enteric fever showed a decline of 6 from the number in the previous week; 2 were recorded in West Ham and 2 in Wigan. The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospital, which had steadily declined in the 12 preceding weeks from 1882 to 1311, had further fallen to 1264 on Feb. 4th last; 130 new cases of this disease were admitted to these hospitals during the week under notice, against 135, 126, and 129 in the three preceding weeks. These hospitals also contained on Feb. 4th 861 cases of diphtheria, 328 of measles, 145 of whooping-cough, and 63 of enteric fever. The 1518 deaths from all causes in London in the week ending Feb. 4th (showing a decline of 20 from the number in the previous week) included 366 which were referred to diseases of the respiratory system, against numbers increasing in the five preceding weeks from 263 to 374. In the 77 towns 178 deaths resulted from different forms of violence, against 169 and 159 in the two previous weeks; and 412 inquest cases were registered. The causes of 34, or 0·6 per cent., of the deaths registered during the week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in London and in each of its eight suburban districts, in Leeds, Bristol, Bradford, Newcastle-on-Tyne, Hull, Nottingham, and in 44 smaller towns; the 41 uncertified causes of death in the 77 towns in the week under notice included 7 in Birmingham, 4 in Sheffield, and 3 each in Liverpool and in Warrington.

In 77 of the largest English towns 8394 births and 5783 deaths were registered during the week ending Feb. 11th. The annual rate of mortality in these towns, which had been equal to 16·4, 16·1, and 16·0 per 1000 in the three preceding weeks, rose to 17·6 in the week under notice. During the first six weeks of the current quarter the recorded death-rate in these towns averaged 16·0 per 1000, and corresponded to the recorded rate during the same period in London. The annual death-rates in the 77 towns during last week ranged from 7·7 in Hornsey, 8·9 in Kings Norton, 9·9 in Walthamstow, and 10·5 in Handsworth (Staffs.), to 24·3 in Stoke-on-Trent, 25·2 in Coventry, 25·4 in Dewsbury, and 29·0 in Stockton-on-Tees. The 5783 deaths from all causes in the 77 towns showed an increase of 528 upon the number returned in the previous week, and included 525 which were referred to the principal epidemic diseases, against 455, 461, and 477 in the three preceding weeks; of these 525 deaths, 249 resulted from measles, 123 from whooping-cough, 58 from diphtheria, 55 (of infants under two years of age) from diarrhœa, 21 from scarlet fever, and 19 from enteric fever, but not one from small-pox. The fatal cases of measles, which had steadily increased during the first five weeks of the current year from 160 to 230, further rose last week to 249, and caused the highest annual rates of 2·2 in Newcastle-on-Tyne, 2·3 in Gateshead, 2·5 in Coventry, 2·9 in Rhondda, 4·8 in St. Helens, and 5·7 in Sheffield. The deaths from whooping-cough, which had been 85, 113, and 116 in the three previous weeks, further rose to 123 in the week under notice; the highest rates from this disease were 1·6 in Bradford, 2·4 in Middlesbrough, 2·9 in Stockton-on-Tees, 3·3 in Norwich, and 3·5 in Warrington. The 58 fatal cases of diphtheria showed an increase of 6 upon the number returned in the previous week and included 23 in London and its suburban dirtricts, 5 in Leeds, 4 in Stoke-on-Trent, and 3 in Liverpool. The deaths of infants under two years of age attributed to diarrhœa which had been 68, 58, and 47 in the three previous weeks, rose again last week to 55. The 21 fatal cases of scarlet fever were equal to the number returned in the previous week; 3 deaths occurred in Portsmouth, 3 in Huddersfield, and 3 in Leeds. The 19 deaths from enteric fever showed a slight increase upon the recent weekly numbers, and included 2 each in London, Croydon, Wigan, Manchester, and Sheffield. The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospital, which had steadily declined in the 13 preceding weeks from 1882 to 1264, had further fallen to 1257 on Saturday last; 147 new cases of this disease were admitted to these hospitals during last week, against 126, 129, and 130 in the three preceding weeks. These hospitals also contained on Saturday last 847 cases of diptheria, 371 of measles, 171 of whooping-cough, and 54 of enteric fever. The 1630 deaths from all causes in London last week (showing an increase of 113 upon the number in the previous week) included 404 which were referred to diseases of the respiratory system, against 366, 374, and 365 in the three preceding weeks. In the 77 towns 187 deaths resulted from different forms of violence, against 159 and 178 in the two preceding weeks, and 407 inquest cases were registered. The causes of 50, or 0·9 per cent., of the deaths registered during the week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leeds, Bristol, West Ham, Bradford, Newcastle-on-Tyne, Leicester, and in 48 smaller towns; the 50 uncertified causes of death in the 77 towns last week included 9 in Birmingham, 8 in Liverpool, 4 in Sheffield, and 3 each in St. Helens and in Hull.

## HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns 768 births and 670 deaths were registered during the week ending Feb. 4th. The annual rate of mortality in these towns, which had been equal to 14·8 and 15·7 per 1000 in the two preceding weeks, rose to 18·2 in the week under notice. During the first five weeks of the current quarter the death-rate in these towns averaged 15·9 per 1000, and was 0·2 above the mean rate during the same period in the 77 English towns. The annual death-rates during the week in the eight Scotch towns ranged from 12·1 and 12·7 in Aberdeen and Greenock to 19·8 in Glasgow and 24·4 in Dundee. The 670 deaths from all causes in the eight towns in the week under notice showed an increase of 94 on the number returned in the previous week, and included 63 which were referred to the principal epidemic diseases, against 51, 43, and 46 in the three preceding weeks; these 63 deaths were equal to an annual rate of 1·7 per 1000, the highest epidemic rates being 2·1 in Greenock and 2·4 in Dundee. Of these 63 deaths from the principal epidemic diseases, 22 resulted from whooping-cough, 18 from diarrhœa, 9 from diphtheria, 8 from scarlet fever, 4 from measles, and 2 from enteric fever, but not one from small-pox. The fatal cases of whooping-cough, which had been 20 and 14 in the two previous weeks, rose to 22, of which 16 occurred in Glasgow, and 2 in Edinburgh. The 18 deaths attributed to diarrhœa (of which 14 were of infants under two years of age) exceeded by 4 the number in the previous week; 8 deaths were registered in Glasgow, 3 each in Dundee and in Aberdeen, and 2 each in Edinburgh and in Greenock. The 9 deaths from diphtheria showed but slight variation from the recent weekly numbers, and included 4 in Glasgow and 2 in Edinburgh. The 8 fatal cases of scarlet fever exceeded the number in the previous week by 2; 5 deaths were recorded in Glasgow, 2 in Dundee, and 1 in Edinburgh. The 4 deaths from measles occurred in Edinburgh. Of the 2 deaths from enteric fever, 1 was registered in Glasgow and 1 in Dundee. The deaths in the eight towns referred to diseases of the respiratory system, which had been 130, 121, and 117 in the three preceding weeks, rose to 138 in the week under notice, but were 12 below the number returned in the corresponding week of last year. The deaths resulting from different forms of violence in the eight towns, which had been 15 and 20 in the two previous weeks, increased again to 27; and 197,

or 29 per cent., of the deaths occurred in public institutions. The causes of 22, or 3·3 per cent., of the deaths in the eight towns were not certified or not stated; in the 77 largest English towns the proportion of uncertified causes of death did not exceed 0·6 per cent.

In eight of the principal Scotch towns 866 births and 728 deaths were registered during the week ending Feb. 11th. The annual rate of mortality in these towns, which had been 15·7 and 18 2 per 1000 in the two preceding weeks, further rose to 19·8 in the week under notice. During the first six weeks of the current quarter the death-rate in these towns averaged 16·6 per 1000, and was 0·6 above the mean rate during the same period in the 77 English towns. The annual death-rates during last week in the eight Scotch towns ranged from 15·3 and 16·8 in Paisley and Aberdeen to 22·3 in Dundee and 23·9 in Greenock. The 728 deaths from all causes in the eight towns last week showed an increase of 58 upon the number returned in the previous week, and included 69 which were referred to the principal epidemic diseases, against 43, 46, and 63 in the preceding three weeks; these 69 deaths were equal to an annual rate of 1·9 per 1000, the highest epidemic rates being 2·8 in Perth and 4·2 in Leith. Of these 69 deaths from the principal epidemic diseases, 33 resulted from whooping-cough, 13 from diarrhœa, 11 from diphtheria, 6 from scarlet fever, 5 from measles, and 1 from enteric fever, but not one from small-pox. The fatal cases of whooping-cough, which had been 14 and 22 in the two previous weeks, further rose to 33 last week, of which 24 occurred in Glasgow, 5 in Leith, and 3 in Edinburgh. The 11 deaths attributed to diphtheria showed a slight increase upon recent weekly numbers, and included 4 in Glasgow, 3 in Edinburgh, and 2 in Leith. The deaths from diarrhœa, which had been 14 and 18 in the two preceding weeks, declined to 13 last week, of which 9 were of children under two years of age. The 6 fatal cases of scarlet fever showed a decrease of 2 from the number in the previous week; 3 deaths were registered in Glasgow, 2 in Greenock, and 1 in Paisley. Of the 5 deaths from measles, 4 occurred in Edinburgh and 1 in Glasgow; the fatal case of enteric fever was recorded in Glasgow. The deaths in the eight towns referred to diseases of the respiratory system, which had been 121, 117, and 138 in the three previous weeks, rose to 161 last week, and were 51 above the number returned in the corresponding week of last year. The deaths resulting from different forms of violence, which had been 20 and 27 in the two preceding weeks, rose again to 28 last week; and 221, or 30 per cent., of the deaths occurred in public institutions. The causes of 19, or 2·6 per cent., of the deaths in the eight towns last week were not certified or not stated; in the 77 largest English towns the proportion of uncertified causes of death last week did not exceed 0·9 per cent.

### HEALTH OF IRISH TOWNS.

In the 22 town districts of Ireland, having an estimated population of 1,163,596 persons, 614 births and 437 deaths were registered during the week ending Feb. 4th. The annual rate of mortality in these towns, which had been equal to 19·3 and 21·3 per 1000 in the two preceding weeks, declined to 19·6 in the week under notice. During the first five weeks of the current quarter the death-rate in these towns averaged 19·9 per 1000, whereas in the 77 largest English towns during the same period the death-rate did not exceed 15·7, and in the eight principal Scotch towns the rate was 15·9 per 1000. The annual death-rate in the week under notice was equal to 24·1 in Dublin, 16·8 in Belfast, 20·5 in Cork, 14·3 in Londonderry, 20·5 in Limerick, and 19·5 in Waterford; in the 16 smallest of the Irish town districts the annual death-rate averaged 16·7 per 1000. The 437 deaths from all causes in the 22 towns showed a decrease of 39 upon the number returned in the previous week, and included 30 which were referred to the principal epidemic diseases, against 25 in each of the two preceding weeks; these 30 deaths were equal to an annual rate of 1·3 per 1000, which was 0·4 below the corresponding rate during the same period in the principal Scotch towns. Of these 30 deaths from the principal epidemic diseases, 9 resulted from whooping-cough, 9 from diphtheria, 5 from enteric fever, 5 from diarrhœa, and 2 from measles, but not one from small-pox or from scarlet fever. The fatal cases of whooping-cough, which had been 9, 11, and 18 in the three preceding weeks, declined to 9 in the week under notice, of which 4 occurred in Dublin and 3 in Londonderry. The deaths attributed to diphtheria, which had been 2, 7, and 3 in the three previous weeks, rose to 9, and included 5 in Dublin and 3 in Dundalk. Of the 5 fatal cases of enteric fever 3 belonged to Dublin and 2 to Limerick. The 5 deaths recorded from diarrhœa and the 2 deaths from measles were registered in Dublin. The deaths in the 22 towns referred to diseases of the respiratory system, which had been 105 and 113 in the two preceding weeks, declined in the week under notice to 107. The 437 deaths from all causes included 148, or 34 per cent., which occurred in public institutions. The causes of 13, or 3 per cent., of the deaths in the 22 towns were not certified either by a registered medical practitioner or by a coroner; the proportion of uncertified causes last week did not exceed 0·6 per cent. in the 77 English towns, and was equal to 3·3 per cent. in the principal Scotch towns.

In the 22 town districts of Ireland, having an estimated population of 1,163,596 persons, 623 births and 538 deaths were registered during the week ending Feb. 11th. The annual rate of mortality in these towns, which had been equal to 21·3 and 19·6 per 1000 in the two preceding weeks, rose to 24·1 in the week under notice. During the first six weeks of the current quarter the annual death-rate in these towns averaged 20·6 per 1000, whereas in the 77 largest English towns during the same period the death-rate did not exceed 16·0, and in the eight principal Scotch towns the rate was 16·6 per 1000. The annual death-rate last week was equal to 27·4 in Dublin, 19·1 in Belfast, 27·4 in Cork, 20·2 in Londonderry, 24·6 in Limerick, and 33·1 in Waterford; in the 16 smallest of the Irish town districts the annual death-rate last week averaged 26·6 per 1000. The 538 deaths from all causes in the 22 towns last week showed an increased of 101 upon the number returned in the previous week, and included 26 which were referred to the principal epidemic diseases, against 29 and 30 in the two preceding weeks; these 26 deaths were equal to an annual rate of 1·2 per 1000, or 0·7 less than the corresponding rate from the same diseases in the principal Scotch towns. Of these 26 deaths from the principal epidemic diseases 8 resulted from whooping-cough, 7 from scarlet fever, 5 from diarrhœa, 2 from enteric fever, 2 from measles, and 2 from diphtheria, but not one from small-pox. The fatal cases of whooping-cough, which had been 11, 18, and 9 in the three preceding weeks, further declined to 8 last week, of which 4 occurred in Londonderry and 3 in Dublin. The deaths attributed to scarlet fever, which had been 1, 1, and 0 in the three previous weeks, rose to 7 last week, 4 of which were registered in Dublin. The 5 deaths from diarrhœa were equal to the number recorded in the previous week; in addition to these deaths, 9 others of infants under two years of age were recorded from enteritis. Of the 2 deaths from diphtheria, which were 7 less than the number returned in the previous week, 1 was recorded in Dublin and 1 in Armagh. The fatal cases of enteric fever and of measles were registered in Dublin. The deaths in the 22 towns referred to diseases of the respiratory system, which had been 113 and 107 in the two preceding weeks, rose to 141 in the week under notice. The 538 deaths from all causes last week included 174, or 32 per cent., which occurred in public institutions. The causes of 13 or 2·4 per cent. of the deaths in the 22 towns last week were not certified either by a registered medical practitioner or by a coroner; the proportion of uncertified causes last week did not exceed 0·9 per cent. in the 77 English towns, and was equal to 2·6 per cent. in the principal Scotch towns.

## THE SERVICES.

### ROYAL NAVY MEDICAL SERVICE.

THE following appointments have been notified:—Fleet-Surgeon E. R. D. Fasken to the *Terrible* and for group of ships of Fourth Division, Home Fleet. Staff-Surgeon: K. H. Jones to the *Magnificent*, and to the *Irresistible* on commissioning. Surgeons: P. M. Rivaz to the *Pomone*, lent temporarily for Dartmouth Cadets' Sick Quarters; T. D. Liddle to the *Edgar* for voyage out, and to the *Torch* on

commissioning; and D. A. Mitchell to the *Terrible* and for group of ships of Fourth Division, Home Fleet.

### ARMY MEDICAL SERVICE.

Colonel Douglas Wardrop, C.V.O., is placed on retired pay (dated Feb. 11th, 1911).

Lieutenant-Colonel Robert I. D. Hackett, from the Royal Army Medical Corps, to be Colonel, vice D. Wardrop, C.V.O. (dated Feb. 11th, 1911).

### ROYAL ARMY MEDICAL CORPS.

The undermentioned Captains to be Majors (dated Jan. 28th, 1911):—James G. Gill, Thomas C. Lauder, Duncan E. Curme, Herbert S. Taylor, Francis J. Brakenridge, Nathaniel J. C. Rutherford, Gilbert J. A. Ormsby, Horace K. Palmer, Francis J. Palmer, Vincent J. Crawford, Arthur L. A. Webb, Howard Ensor, D.S.O.

Lieutenant-Colonel Samuel Townsend retires on retired pay (dated Feb. 8th, 1911).

The undermentioned Lieutenants are confirmed in their rank:—Wilfred W. Treves, Charles H. H. Harold, Eric L. Fyffe, Robert F. Bridges, Thomas J. Hallinan, John D. Bowie, Charles H. Stringer, Guy O. Chambers, John K. Gaunt, Leslie F. K. Way.

Lieutenant-Colonel A. E. Morris, on return from Kamptee (India), has been posted to the Cork District and appointed in charge of the Military Hospital at Cork in succession to Lieutenant-Colonel T. E. Noding, transferred to Hilsea. Lieutenant-Colonel G. Cree, from Madras, has taken up duty in the London District. Lieutenant-Colonel J. H. Daly has been transferred from Tipperary to Limerick. Lieutenant-Colonel C. Birt, from Dublin, has joined at the Curragh. Lieutenant-Colonel C. W. Johnson, from Gibraltar, has been appointed for duty in the Southern Command. Major D. Harvey, Specialist in the Prevention of Disease Eighth (Lucknow) Division, has been granted six months' leave of absence home from India. Major F. Smith, D.S.O., Sanitary Officer, Second (Rawal Pindi) Division, has been transferred from Murree to Rawal Pindi. Major G. B. Riddick, from Rangoon, has joined for duty at Maymyo. Major S. J. C. P. Perry, from Dover, has arrived in India. Major S. L. Cummins has been placed on special duty at the Royal Army Medical College, Grosvenor-road. Major A. H. Waring, on completion of a tour of service in India, has been posted to Portland. Major J. C. Jameson, from Khartoum, has taken up duty at Cairo. Major G. B. Carter has been placed under orders to embark for India on March 3rd for service with the Northern Army. Major R. J. Blackham, sanitary officer of the First (Peshawar) Division, has been placed on special duty for three months in connexion with the St. John Ambulance Association (Indian Branch). Major W. G. Beyts and Major W. H. Nickerson, V.C., have embarked for a tour of service in India on the transport *Dongola* from Southampton. Major J. H. Campbell, D.S.O., from Mauritius, has taken up duty as Recruiting Medical Officer in the London District. Major F. R. Buswell, from the London District, has been posted to the Station Hospital at Jubbulpore. Captain J. A. Douglas, at present serving in the Dublin District, has been placed under orders for a tour of service on the West Coast of Africa (Sierra Leone). Captain L. L. G. Thorpe has been transferred from the Royal Victoria Hospital, Netley, to Tidworth Park. Captain M. B. H. Ritchie, from Murree, has taken up duty at the station hospital, Rawal Pindi. Captain A. W. Gater, on return from India, has been posted to the Cork District. Captain S. M. Adye-Curran has been appointed in charge of the Brigade Research Laboratory at Sialkot. Captain J. T. McEntire has been transferred from Newcastle for duty in the Irish Command. Captain F. C. Sampson, from Bloemfontein, has been appointed to the military hospital at Potchefstroom. Captain F. W. Dawson, at present serving at Dundalk, has been placed under orders to embark for India on March 3rd next for duty with the Southern Army. Captain E. G. R. Lithgow, on return from Aden, has been appointed to the Eastern Command. Captain W. F. H. Vaughan, on return to duty from leave of absence, has been posted to Cosham. Captain J. M. H. Conway has been transferred from Kilbride to Dublin. Lieutenant G. S. Parkinson, Lieutenant W. Mathieson, Lieutenant J. James, and Lieutenant A. M. Pollard have embarked for a tour of service in South Africa. Lieutenant M. J. Williamson has been transferred from Tidworth Camp to Cardiff.

### INDIAN MEDICAL SERVICE.

The King has approved of the admission of the undermentioned gentlemen to the Indian Medical Service:—To be Lieutenants (dated July 30th, 1910): Phirozshah Byramji Bharucha, Richard William George Hingston, John Bailey Tackaberry, Charles Newton-Davis, Reginald Charles Clifford, Clive Newcomb, Henry Edward Shortt, Thomas Arthur Hughes, Latafat Husain Khan, Robert de Stretton Berkeley Herrick, Hargobind Lal Batra, Murray Purvis, Walter Oliphant Walker, Duncan McNab Taylor, and Vincent Philip Norman. To be Lieutenants on probation (dated Jan. 28th, 1911): John Scott, Alister Ralph Speirs Alexander, Frederick William Hay, "Kanwar" Indarjit Singh, Sidney Milverton Hepworth, Harry Slater Cormack, George Tate, George Selby Brock, Edward Slade Goss, John Frederick Henry Morgan, Krishnan Gopinath Pandalai, Jyoti Lal Sen, Charles Albert Wood, and Percival Sandys Connellan.

The King has approved of the retirement of Lieutenant-Colonel Hastings Norman Victor Harington (dated Nov. 28th, 1910), and of Major Charles Thomson (dated Jan. 30th, 1911).

Lieutenant-Colonel A. Street has been granted six months' extension of furlough on medical certificate by the Secretary of State for India. Lieutenant-Colonel C. H. L. Meyer has been appointed to officiate as Principal of the Grant Medical College at Bombay in succession to Lieutenant-Colonel H. P. Dimmock. Major J. H. McDonald has taken up duty as Presidency Surgeon, Bombay (Second District) in succession to Lieutenant-Colonel J. Crimmin, V.C., C.I.E. Major J. G. Murray has been appointed to officiate as Professor of Materia Medica at the Medical College, Calcutta, vice Lieutenant-Colonel J. T. Calvert. Captain M. I. Quirke has returned to India from leave. Captain A. W. Tuke has been appointed by H.E. the Governor of Bombay to be a Civil Surgeon of the Second class and to officiate as Resident Surgeon to St. George's Hospital in Bombay. The services of Captain C. L. Dunn, assistant plague medical officer at Jullundur, have been placed at the disposal of the United Provinces of Oudh and Rohilkhand. Captain L. P. Brassey has been appointed to officiate as Civil Surgeon at Meiktila during the absence on leave of Captain H. A. Dougan. Captain A. F. Baboneau, assistant plague medical officer at Amritsar, has been appointed District Plague Medical Officer at Ferozepore. The special leave of absence granted to Captain N. S. Wells, civil surgeon, United Provinces, has been commuted to furlough on medical certificate and extended by six months.

### SPECIAL RESERVE OF OFFICERS.

*Royal Army Medical Corps.*

The under-mentioned to be Lieutenants (on probation): Robert McCheyne Linnell (dated Jan. 6th, 1911); William Crymble (dated Jan. 13th, 1911); and Charles Alfred Bignold (dated Jan. 17th, 1911).

### TERRITORIAL FORCE.

*Royal Army Medical Corps.*

2nd East Lancashire Field Ambulance, Royal Army Medical Corps: William James Purves to be Lieutenant (dated Dec. 21st, 1910).

2nd South Midland Field Ambulance, Royal Army Medical Corps: Lieutenant-Colonel Charles T. Griffiths reverts at his own request to the rank of Major (dated Feb. 15th, 1911). Major Charles T. Griffiths resigns his commission (dated Feb. 15th, 1911).

*Attached to Units other than Medical Units.*—Major Alfred C. Tunstall is retired, under the conditions of paragraph 116, Territorial Force Regulations, and is granted permission to retain his rank and to wear the prescribed uniform (dated Feb. 15th, 1911).

*For attachment to Units other than Medical Units.*—William Lang Hodge to be Lieutenant (dated Dec. 15th, 1910). Dudley Raymond Harris to be Lieutenant (dated Jan. 7th, 1911).

---

THE annual dinner of the West London Medico-Chirurgical Society will take place at the Wharncliffe Rooms, Hotel Great Central, Marylebone-road, W., on Feb. 22nd, at 7.30 P.M.

# Correspondence.

"Audi alteram partem."

## CHARLES BELL AND THE MOTOR AND SENSORY FUNCTIONS OF SPINAL NERVES.

*To the Editor of* THE LANCET.

SIR,—In his address on Sir Charles Bell published in THE LANCET of Feb. 4th, p. 290, Professor Arthur Keith repeats the ordinary statement that Sir Charles Bell discovered that the anterior root of a spinal nerve is motor, the posterior root sensory. For his facts he relies on authorities no further back than 1867, and although he makes mention of the privately printed pamphlet of 1811 entitled, "Idea of a New Anatomy of the Brain," he does not appear to have consulted that pamphlet in the original. I took occasion to do so 20 years ago when preparing a text-book of physiology. After a careful examination of the original pamphlet of 1811, as well as of Bell's first paper on the nerves in the Philosophical Transactions of 1821, 1830, and 1836, and of the reprint in 1824, I came to the conclusion that Bell had missed making the discovery. I wrote the following passage with original publications of Bell and of Magendie at my elbow: "These facts [i.e., anterior root motor, posterior sensory], inclusive of those dependent on recurrent sensory fibres, were discovered by Magendie (1822). Charles Bell (1811), to whom they are commonly ascribed, observed motion on excitation of the anterior roots of a recently killed animal and inferred that the anterior or 'cerebral' roots are motor and sensory, and that the posterior or 'cerebellar' roots serve to govern vital actions."[1]

I am, Sir, yours faithfully,

A. D. WALLER.

Physiological Laboratory, University of London, S.W.

## TRANSPERITONEAL CYSTOTOMY FOR TUMOUR OF THE BLADDER.

*To the Editor of* THE LANCET.

SIR,—When reading the interesting paper under this title which appeared in THE LANCET of Jan. 28th, p. 214, from the pen of Mr. Seton Pringle, I remembered a case of epithelioma of the bladder operated upon by this method by Mr. Rutherford Morison during the time that I acted as his house surgeon. On referring to the hospital notes I find the date was so long ago as Oct. 17th, 1899, but as the case has never been published Mr. Pringle could not have been aware of its performance.

The patient was a woman of 48, and the growth, of the size of a florin, lay just above the left ureteral orifice. The peritoneum was freely opened, enabling the growth to be widely excised and the bladder repaired by immediate suture. Recovery was uninterrupted, and when the patient left the hospital on Nov. 2nd she was able to hold urine for three hours, and by February she did not require to get up at night. A year after the operation a definite recurrence was noticed in the pelvic glands, and when last seen, in March, 1901, although there were widespread deposits in the abdomen and left side of the neck, the patient had no bladder trouble whatever.

Since the time that I had the privilege of assisting Mr. Morison with this operation I have always kept the advantages of transperitoneal cystotomy before me, but it was not until January, 1909, that a suitable case came into my own hands. At that time I removed a large epithelioma from the bladder of a nurse, together with some enlarged glands from the right iliac artery, and so far she remains well and without signs of recurrence. Since then I have twice deliberately opened the peritoneum under similar circumstances—once in performing total removal of the male bladder for cancer, and once in assisting me to close an old-standing suprapubic fistula.

I think it may be a distinct advantage when operating for malignant bladder growths to make the opening of the peritoneum the first step in order that the condition of the glands and the abdominal aspect of the growth may be examined. As a result, it may be deemed unwise to proceed in the hope of a radical operation, or the glands may be safely dealt with and the area packed off before danger of contamination from the opened viscus.

I am, Sir, yours faithfully,

Newcastle-upon-Tyne, Jan. 31st, 1911. G. GREY TURNER.

## A METHOD OF SERUM DIAGNOSIS FOR TUBERCLE.

*To the Editor of* THE LANCET.

SIR,—I quite understand that Dr. d'Este Emery was unable to go into full details in his letter of Jan. 7th, and I appreciated very much the kindliness of his criticisms. In reply to his letter of Jan. 21st it is clear that his method gives very different results to mine. I cannot by my procedure detect the presence of antibodies in normal sera, or in the sera of patients who have recovered from tubercle.

Dr. Emery, as far as I can judge, finds sufficient immune bodies in the sera of apparently healthy people to deviate complement in 30 minutes. He therefore from his point of view insists that an accurate standardisation of the tubercle emulsion is necessary. It must be obvious that if neglect of this point had affected my results I would also have resorted to this measure. I find that ten times the quantity of the emulsion (equal to 1·6 per cent. of bacillary substance) that I ordinarily use fails to deflect complement in my serum, even after 12 hours' contact at 60° F. A further proof of this is that equal parts of the emulsion and my serum incubated for two hours are unable to cause the phagocytosis of tubercle bacilli, but it will do so when mixed with an equal part of heated serum.

Each sample of dried tubercle bacilli is tested against a normal and a tuberculous serum, as the efficacy of the various samples varies. Generally, a sample which gives good opsonic differences gives also good complement fixation results. I estimated three of the emulsions used during the last four weeks, and found that after 15 minutes in a very fast electric centrifuge there was a deposit of bacilli equal to 1·6 per cent. of the total bulk of fluid in each case. I keep a standard emulsion made up with 1 per cent. salt and 0·5 per cent. carbolic, and approximate each newly made emulsion to this standard. I find that centrifuging for 30 minutes fails to precipitate all the bacteria. The bacteria I employ are fresh, and are killed by steaming at 100° C. for one hour; they are then dried at a low temperature. The emulsion is neutral, and deposits a very little in 24 hours. It is made freshly every second day, and is never heated. With each test two or three normals are put up.

I find that immune bodies soon disappear from the sera of tuberculous patients on recovery—e.g., two cases of tubercle of joints and two of lung which lost the reaction in six weeks with improved health. When the disease is slight or the lesion quiescent exercise and massage are necessary to obtain a reaction. When the disease is acute and the opsonic index above normal, 1-200 000th milligramme of tuberculin, inoculated, is able to nullify the reaction. This suggests that the quantity of immune bodies may be extremely minute. The special advantage of this complement fixation test is that a decided positive determination is obtained, frequently impossible by other methods. When there is only a reduction of hæmolysis the experiment is repeated with 20 cubic millimetres of emulsion. If there is still a trace of hæmolysis I read the result negative. If the result is negative after two or three examinations and the physical signs show active disease I consider that tubercle can be excluded. Further observations will also demonstrate, I believe, that this fixation test can be relied upon as an indication of the cure of tubercle.

As regards hæmolysis, I find that abnormal sera have greater destructive power on sheep's corpuscles than normal sera, unless the disease is severe and the condition of the patient bad. As regards the opsonic index, I believe that this is only another method of demonstrating the Bordet-Gengou reaction. The same factors which influence hæmolysis also appear to influence phagocytosis. When the quantity of complement is constant an increase of specific

[1] An Introduction to Human Physiology, third edition, pp. 485–6. Bibliography at p. 619, first edition.

immune body increases the phagocytosis. In the absence of either immune body or complement the phenomenon ceases. An excess of immune body deflects complement in the presence of the specific bacillus.

Hæmolytic observations show that a subnormal opsonic index in a patient suffering from tubercle is frequently accompanied by a high degree of immunity, and may be regarded as a favourable sign, this contrary result being due to fixation of the complement in the opsoniser. I think that a supernormal index is due to the presence of immune bodies, but not sufficient in quantity to fix the majority of the complement. This condition is therefore more unfavourable than a normal or a subnormal index. A natural fall of the index to normal may be regarded as a favourable sign, as showing an increase of the immune bodies. The sudden fall of a supernormal index after inoculation I think is due to the neutralisation of the immune bodies, and the rise of a subnormal after an intravenous inoculation to a reduction of the immune bodies.

Some of the experiments demonstrating these points are as follows: 1. Antigen of heart muscle greatly reduces (on previous incubation) the phagocytosis of staphylococci with syphilitic sera, but not with normal sera. 2. If a serum with a constant subnormal index—e.g., 0·5—be heated to 52° C. for 15 minutes and then mixed with an equal part of tubercle emulsion and left for two hours at room temperature (60° F.), this, when incubated with an equal part of de-immunised serum and corpuscles, will give a phagocytic count from two to three times as great as normal serum. 3. If 4 parts of heated and 1 part of unheated serum be incubated with tubercle emulsion (60° F., two hours) and then 1 volume of this be incubated for 15 minutes with 1 volume of staphylococci and 1 volume of leucocytes, a normal serum shows three to four times more phagocytosis (T.B.) than the tuberculous. The staphylococci are employed to further reduce the complement.

As regards hæmolytic observations by Hecht's method, its convenience is its advantage, and as heated serum is employed the amboceptor difficulty is decreased. In case of difficulty, or when the serum is old, I use my own fresh serum and the patient's heated serum.

Since sending my article for publication I have altered the technique on a few points: (1) The serum is heated for 15 minutes at 125° F. (52° C. nearly) in place of 56° C. for ten minutes; (2) the fixation reaction is allowed to take place at room temperature (60° F.) in place of 98° F.; (3) the tubercle emulsion is added last, after the serum has been diluted with hypotonic salt made with tap-water; and (4) two hours' old serum can be used.

I am, Sir, yours faithfully,

Ealing, Feb. 11th, 1911. V. NESFIELD.

## NOTIFICATION OF MEASLES.

*To the Editor of* THE LANCET.

SIR,—I am instructed by the executive council of this league to inform you that at its meeting held on Friday last the following resolution was unanimously passed:—

That in view of the widespread incidence and considerable mortality amongst the children of the poor, and having regard to the very serious consequences of measles, that disease ought to be compulsorily notifiable.

We should be much obliged if you would notice this resolution in an early issue of your journal.

I am, Sir, yours faithfully,

J. HALFORD,
Secretary, National League for Physical Education and Improvement.

Tavistock-square, W.C., Feb. 13th, 1911.

CHICHESTER INFIRMARY.—At the annual meeting of the supporters of the Chichester Infirmary and Dispensary on Feb. 9th plans were adopted for reconstructing the old building, which is 85 years old, as a memorial to King Edward, who so frequently visited it during his stays at Chichester. The plans provide for bringing the building thoroughly up-to-date in every way, but at the same time the old character of the building will be strictly preserved. The cost of the scheme is roughly put at £14,000, towards which Mr. William James, of West Dean Park, King Edward's frequent host at Chichester, has given £10,000.

# BRISTOL AND THE WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

### *Bristol Eye Hospital.*

THE 100th annual meeting of the subscribers to the Bristol Eye Hospital was held on Feb. 6th under the presidency of Sir Charles Cave. The medical report stated that for the year ended September, 1910, 474 in-patients were admitted and 7061 out-patients were treated. The financial statement showed the institution to be free from debt. The income from invested funds was about £500 per annum, and the committee states that in order to carry out the work of the charity satisfactorily the subscription lists should be raised to a sum of £1000 annually. The profits of the fête which was held last year amounted to over £1600, and enabled the deficit balance which existed against the hospital to be wiped out and also to establish a small nurses' home situated close to the hospital, where the nurses will have more convenient quarters, and the rooms which had been previously occupied by them can now be used for the accommodation of patients.

### *University Lectures on Social Subjects.*

A series of evening lectures on social questions is being given by various speakers at the University of Bristol. The third of these, on public health, was recently delivered by Dr. D. S. Davies, the medical officer of health, who is also the lecturer on public health in the University. He gave a very interesting account of the health of Bristol in the Middle Ages, alluding to the devastating plague of 1349, which killed half the city, and to the three leper hospitals which are known to have existed in the fourteenth century. Even so recently as 1849, cholera claimed 2000 victims in Bristol. The death-rate, which in 1910 was 11·8, was 22·7 70 years ago. He hoped that the University would soon undertake the instruction and registration of women who would combine a practical knowledge of nursing with a knowledge of administrative work and hygiene. The fourth lecture, on the treatment of the feeble-minded, was given by Mrs. Hume Pinsent, a member of the recent Royal Commission.

### *A Hospital Nurse's Brave Conduct.*

The committee of the Bristol General Hospital at a recent meeting congratulated one of the nurses on the remarkable bravery which she showed in dealing with a delirious patient. About 4 A.M. the man in question, a burly dock-labourer suffering from pneumonia, suddenly and without warning became delirious and jumped on the window-sill. The nurse, who was just coming into the ward, seized him, but he broke a pane of glass and climbed out on a sloping roof which lies just outside the window. The nurse followed him through the broken window and struggled with him on the roof, which is 10 feet wide and protected from a sheer drop of 30 feet by a parapet which is about a foot high. In the struggle he broke a skylight and fell through it to a verandah 16 feet below, breaking several ribs. The nurse fortunately escaped, and though the patient died his condition was so bad that he could not have recovered even if there had been no accident.

### *The Lord Mayor's Hospital Sunday Fund in Bristol.*

The collections devoted to this fund and handed in by Feb. 10th have amounted to £1201 0*s.* 9*d.*, as compared with £1084 0*s.* 5*d.* received last year by the same date. There are about 200 collections yet to come in, 327 having been received so far.

### *Clifton Dispensary.*

At the annual meeting of the friends of this charity, held on Feb. 6th, it was stated that the admissions to treatment during 1910 included 2420 medical, 312 surgical, and 71 midwifery cases. In spite of an increase of £20 from subscriptions, donations, and collections, there was an adverse balance of £8 8*s.* 4*d.* at the end of the year.

### *The Importation of Diseased Beef in Bristol.*

Dr. D. S. Davies has reported to the health committee of the city of Bristol the discovery by one of his food inspectors of disease in consignments of beef arriving in the port of Bristol from Australia. Similar observations had been made

in the port of London. Nodular masses were found embedded in the meat which consisted of aggregations of a parasitic worm, spiroptera reticulata. Although the ingestion of this dead worm would not infect human beings, yet such meat is clearly unfit for food, and steps are being taken in Australia to prevent exportation of diseased portions. The Bristol investigations applied to 500 forequarters, 306 of which were affected, and 500 hindquarters, 64 being affected.

*Backward Children.*

At a meeting of the Bristol branch of the Parents' National Education Union held on Feb. 9th at Clifton College, under the presidency of Mr. J. E. King, headmaster of the College, an interesting lecture was given by Dr. G. H. Savage on Backward Children.

*Taunton and Somerset Hospital.*

The annual meeting of the subscribers to the Taunton and Somerset Hospital was held at Taunton on Feb. 9th under the presidency of the Hon. E. B. Portman. The medical report was satisfactory, but the financial statement showed a deficit of £1710 against the institution. It was decided that in the summer a strong effort should be made to celebrate the centenary of the hospital by the establishment of an endowment fund. It is proposed to try to raise £30,000.

*The Water-supply of Chard (Somerset).*

At the last meeting of the Chard town council it was decided to purchase land for the proposed new water scheme for the town. The water-supply will be obtained by a gravitation scheme, and the cost of the undertaking will be about £8000.

*The Care of the Feeble-minded.*

The Taunton board of guardians has recently proposed a scheme whereby all the pauper idiots, imbeciles, and epileptics in the various workhouses in Somerset should be placed in one institution in that county. A meeting, at which representatives from every union in Somerset were present, was held at Taunton last week. After a considerable discussion it was unanimously decided to approach each board of guardians in the county and ascertain whether one of these bodies could allow a workhouse or a portion of such an institution to be used for the proposed scheme.

*Peter Pearson Johnson, M.B., Ch.B. Edin.*

Dr. P. P. Johnson died at his residence, Henley Lodge, Yatton, Somerset, on Jan. 29th, in his fifty-eighth year. Dr. Johnson graduated M.B., Ch.B. of Edinburgh in 1877, and shortly afterwards went to Yatton, where he soon acquired an extensive practice. He was district medical officer for Yatton, surgeon to the employees of the Great Western Railway and the post office, and also certifying factory surgeon. Dr. Johnson took a great interest in all local matters, and was formerly chairman of the Yatton parish council. He was a prominent Freemason and a strong churchman. He was very popular in Yatton, and much sympathy is felt there for his widow and children. The funeral took place on Feb. 1st and was largely attended, many Freemasons being present, including Colonel W. Long (Provincial Grand Master of Somerset). Representatives of the Yatton parish council, the Oddfellows, the Church of England Men's Society were also present, as well as the Dean of Bristol (Dr. Pigou) and a large number of local members of the medical profession.

*The Research Defence Society.*

A local branch of the Research Defence Society for the "Three Towns" has been formed at Plymouth.

*Medical Officer of Health of Cornwall.*

At a meeting of the Cornwall county council held on Feb. 8th three candidates were interviewed in connexion with the appointment of medical officer of health for the county. Mr. Robert Burnet, M.Sc., M.B., Ch.B. Vict. and Liverp., D.P.H. Birm., was eventually appointed, securing 41 votes against 25 and 3 obtained by the other applicants respectively. The salary of the post is £500 per annum, increasing by annual increments of £20 to £600, in addition to travelling expenses. Dr. Burnet is at present medical officer of health of Bury, medical officer to the education authority, and medical superintendent of the Bury and District Joint Hospital Board fever and small-pox hospitals.

Feb. 14th.

# WALES.

**(FROM OUR OWN CORRESPONDENT.)**

*Medical Officers of Health for Brecknockshire and Cardiganshire.*

THE Brecknockshire county council has elected Mr. J. C. Bridge, medical officer of the Dunfermline Trust, as medical officer of health and school medical officer of the county of Brecknock at an annual salary of £500 in addition to travelling and office expenses. When the election took place on Jan. 27th exception was taken by some members of the council to the fact that among the six candidates who had been selected by a committee to appear before the council not one could speak Welsh. A member of the committee thereupon expressed regret that the salary offered was so small, and stated that if it had been higher a Welsh-speaking official might have been appointed. For the position of medical officer of health and school medical officer of Cardiganshire there were only five applicants, the salary, which includes travelling expenses, being £450 per annum. Two of the candidates withdrew their applications, and at the meeting of the council on Feb. 9th Mr. R. W. Rees, who was at one time medical officer of health of the Llandilofawr urban and rural district councils, was elected.

*Pollution of the River Wye.*

The water-supply of the city of Hereford is drawn from the river Wye, into which the untreated sewage of the town of Hay is discharged about 30 miles above the Hereford intake. After trying in vain to induce the Hay district council to take suitable steps to prevent the pollution the Hereford corporation has at length decided to take definite action, in conjunction with the county council, with a view of compelling the Hay authority to undertake the necessary remedial measures.

*Cardiff Infirmary: Scheme for Payment by Patients.*

The board of management of the Cardiff Infirmary has decided to carry out experimentally for one year a scheme under which each patient will be expected to contribute to the funds of the institution unless obviously too poor to do so. It is proposed that each in-patient should pay sixpence per day and each out-patient threepence per week. At the festival dinner of the infirmary held on Jan. 25th the sum of £2800 was subscribed towards the funds of the institution. Lord Tredegar, who presided, pointed out how absolutely essential it was to have a medical school attached to a large infirmary. He referred also to the necessity for adequate accommodation for research work.

*Aberystwith Infirmary.*

The Aberystwith Infirmary and Cardiganshire General Hospital was established in the year 1821 as a dispensary. It has now accommodation for 27 patients. During 1910 there were treated in the wards 161 patients, and 1004 persons attended the out-patient department. The expenditure amounted to £919 and the income received was £752. The subscription list of £161 seems a meagre one; indeed, if it were not for the assistance rendered from a special trust fund, which contributed over £500 in 1910, it would be impossible to carry on the institution. Sir John Williams has recently been appointed consulting physician to the infirmary.

*Pontypridd Workhouse.*

The Pontypridd Union is a large one, including as it does not only the town of Pontypridd but also the adjoining Rhondda urban district. The workhouse is situated in the centre of Pontypridd, and in recent years there has been established a secondary workhouse for old people in the Rhondda, while in another direction the children are housed in cottage homes. The nursing accommodation at the older workhouse is quite inadequate for the needs of the institution. In a special report upon the matter, Mr. Howard Davies, the workhouse medical officer, has urged very strongly the necessity for remedying the existing conditions. There is a lack of accommodation for the nurses when they are on duty, and the only sitting-room provided for them is badly ventilated, dingy, cheerless, and altogether uncomfortable. The bathrooms and annexes are quite out of date, so that the ward utensils have to be cleansed in the same sink with plates, mugs, cups, &c. A subcommittee of the board of guardians

has recommended that a separate building should be provided for the nurses and that the bathrooms and annexes should be reconstructed.

*Housing in Monmouthshire.*

In a report presented to the Local Government Board in 1905 Dr. W. W. E. Fletcher referred to the unsatisfactory condition of many of the houses in the urban district of Nantyglo and Blaina in the Monmouthshire colliery district. Many of the circumstances which he described appear to be still in existence and are referred to in a report which has recently been made by the medical officer of health of the district, Mr. H. C. Bevan. Of 960 houses in one particular locality there are 442 with no through ventilation, and 187 have no system of drainage. Instances are given in the report of back-to-earth cellar dwellings which are occupied by families consisting of from five to eight persons, and one case in which a two-roomed cellar dwelling was occupied by two adults and seven children.

Feb. 13th.

## LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

*Liverpool School of Tropical Medicine: Plague in China; Sleeping Sickness; Another Expedition to Rhodesia.*

AT a meeting of the School of Tropical Medicine held recently, Mr. W. H. Lever (the chairman) presiding, it was unanimously resolved to send the following telegram through the Chinese Minister to the Chinese Government, in view of the great ravages caused in Manchuria at present by the plague, viz. :—

The President and Committee of the Liverpool School of Tropical Medicine offer to the Chinese Government the services of an experienced commissioner to proceed to Manchuria and assist in combating the outbreak of plague. Would be much obliged if your Excellency would communicate the offer to the proper quarters and advise the school whether offer accepted.

The following telegram has been received in reply :—

Secretary Milne, Tropical School, Liverpool,—Many thanks for your telegram and your kind offer. Question under urgent consideration with British Government, who will associate themselves with the measures to be taken. CHINESE MINISTER.

It will be of melancholy interest to note that the devoted and self-sacrificing missionary, Dr. A. F. Jackson, who has just fallen a victim to the plague in his endeavours to assist, by his skilled knowledge, the terrified inhabitants of Manchuria, was quite recently a student at the Liverpool School of Tropical Medicine. The other two martyrs of the school were Dr. Walter Myers and Dr. J. Everett Dutton.

The British South Africa Company has decided upon the despatch of a special commission with the object of investigating sleeping sickness in Rhodesia. The commission will consist of Dr. Aylmer W. May, principal medical officer of Northern Rhodesia; Dr. A. Kinghorn, of the Liverpool School of Tropical Medicine; Mr. H. Leach, of Northern Rhodesian Medical Service; Mr. O. Silverlock, entomologist; and Mr. Jollyman, bacteriologist. All the commissioners, with the exception of Dr. May and Dr. Kinghorn, are already in Africa. Dr. Kinghorn will sail from England on Feb. 18th, and will be followed later by Dr. May. An expedition sent out by the Liverpool School of Tropical Medicine is already on its way to the Congo, under Professor J. L. Todd, well known in connexion with sleeping-sickness research, and two assistants; and it is proposed that a further Commission shall go from this country to conduct separate investigations in another part of the Congo. Dr. May informs the Press Association that sleeping sickness in the Luangwe Valley of North-east Rhodesia, where the Chartered Company's commission is about to work, is of an entirely different type from that of ordinary sleeping sickness, inasmuch as it is evident that it is not transmitted by the glossina palpalis. This insect does not exist within 200 miles of the Valley, and the majority of those attacked have never been in the palpalis area. It is suggested that this disease is carried by the morsitans fly, an insect which, unlike the palpalis, is not confined to well-defined limited areas in the neighbourhood of water, but is distributed over large areas. It does not seem to follow, however, that because the morsitans is a disease-carrier at one altitude it is necessarily equally dangerous under other climatic conditions. Five Europeans have been stricken with this form of sleeping sickness, of whom three are dead and two are under treatment. Dr. May expresses the opinion that if the conditions agreed to by the conference which has just been held at the Foreign Office are carried out there is not much danger of the disease spreading from the Congo southwards with the extension of the railway. With proper precautions there is no cause for alarm, as the conditions in Northern Rhodesia are entirely unsuitable to the spread of the malady. Dr. Kinghorn is one of the most distinguished workers in the Liverpool School of Tropical Medicine, with which he has been associated during the last five years. He has been on two previous expeditions in Africa for the purpose of investigating the causes of sleeping sickness. His investigations have been varied and extensive.

*Death of Dr. A. F. Jackson.*

The death of Dr. A. F. Jackson on Jan. 26th, from plague, at Mukden in Manchuria, came as a great shock to his numerous friends in Liverpool. Dr. Jackson left this country last autumn to begin work as a medical missionary in Manchuria, where he arrived in November last, so that he died on the very threshold of a life's work which was full of promise. He was born in Oxton, Cheshire, 26 years ago, and was educated at Merchant Taylors' School and at the University of Cambridge. He had a brilliant career at Cambridge, and afterwards studied medicine at the University of Liverpool, where he graduated as M.B., C.M. He also received the Diploma of Tropical Medicine.

Feb. 14th.

## SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

*The Carnegie Trust.*

THE ninth annual meeting of the Carnegie Trust was held on Feb. 7th at the Westminster Palace Hotel, London, the Earl of Elgin presiding. The ninth annual report for the year 1909–10 submitted by the executive committee showed that the success of the research scheme of the Trust was being well maintained. The sum of £6824 had been expended upon fellowships, scholarships, and grants, and £2454 upon the laboratory, towards which latter the Royal College of Physicians of Edinburgh and the Royal College of Surgeons of Edinburgh together contributed £1025. The class fees paid during the year amounted to £48,540 2*s*., an increase of £1184 6*s*. 6*d*. as compared with the preceding year. The beneficiaries in the winter session 1909–10 numbered 3676 and in the summer session 1353. The average amount paid per beneficiary was £12 12*s*. 9*d*. Certain other beneficiaries had received fees for classes taken outwith the academic year and others for the summer vacation courses in Edinburgh. The executive committee called the attention of the Trust to the fact that the increasing expenditure on class fees made it possible, if not probable, that there would be a deficit against the transactions under Clause B. The committee considered that as they could not protect themselves against the occurrence of a deficit in future years under the present system it ought to be amended without delay. They must in the first place announce that they could not continue to pay the fees in full. Secondly, the system of paying for separate classes must be abandoned. If the system of composite fees were adopted by the universities it might be possible for the Trust to pay such a proportion of those fees as their funds permitted. If the universities did not succeed in making such an arrangement it might be necessary for them to determine a scale of fees on the same principle for themselves. It seemed reasonable that the interests of beneficiaries already on the roll should be protected as far as possible. Thirdly, the amount they could afford to pay would be more easily determined if some scheme could be adopted for enrolling the names of applicants in advance. Fourthly, it could cause no hardship to require students who had already been receiving payment to inform them before the end of the summer session whether they intended to apply again in October or to require new applicants to give a similarly early notice. Fifthly, it did not in the least follow that if these suggestions were adopted the scale of

their allowances would become unsettled or would vary from year to year, or that the discussion in the future of further changes would be precluded. The main objects of these proposals were (1) to prevent any chance of the fund becoming bankrupt for a longer period than the year now current; and (2) to adopt a machinery that might be made effective for more than one occasion if need be. The committee referred to allegations which had been made that the payment of fees was accepted by students whose private means were sufficient to defray their expenses. In several cases where gross abuse had been alleged inquiry had shown an amount of misrepresentation and exaggeration which had rendered any action inadvisable. The committee called attention to the fact that up to Sept. 30th, 1910, 75 beneficiaries had voluntarily refunded the class fees paid by the trust on their behalf, the sum amounting in all to £1689 1*s*. 4*d*. It was not to be expected that in the early years of the trust beneficiaries would be in a position to avail themselves of this privilege; and the fact that in the past year fees to the amount of £549 had been repaid—more than double the amount paid in any previous year—was an undoubted proof that the system could, and did, encourage honourable sentiments. Lord Elgin, in moving the adoption of the annual report, drew attention to the satisfactory nature of the reports relating to research. Referring to the payment of fees, he was confident that it was not true that general or flagrant abuses or misappropriation of the fund had prevailed, while the gratifying increase in the amount of fees repaid showed that students were not unwilling to avail themselves of opportunities to discharge honourable obligations. He pointed out that the increase of beneficiaries was practically the same as the increase in matriculated students in the last nine years; this might be merely a coincidence, but the increase might be due to the development of the secondary schools, and these students might be well qualified for assistance. The motion of the Chairman was seconded by Mr. Haldane, who referred especially to the importance of the work of the Carnegie Trust in stimulating research. Sir Arthur Rücker then spoke in appreciation of the work done by the Trust. Lord Balfour of Burleigh moved a vote of thanks to the Chairman, which was seconded by Lord Reay. Principal Sir William Turner referred to the enormous benefits conferred on the Scottish universities by the munificent benefaction of Mr. Carnegie and referred in complimentary terms to the work of the executive committee.

*Complimentary Dinner to Dr. William Craig of Edinburgh.*

On Feb. 8th the Fellows of the Edinburgh Obstetrical Society entertained Dr. William Craig to dinner at the Caledonian Station Hotel on his retirement from the treasurership of the society, a post that he had held for 35 years. About 40 Fellows were present, and the President of the society, Dr. F. W. N. Haultain, occupied the chair. The toast of the evening was proposed by Sir A. R. Simpson, who, in presenting Dr. Craig with a silver tea and coffee service, referred to the great services he had rendered to the society.

*Reconstruction of Hospitals in Glasgow.*

For many years the hospital accommodation in Glasgow has been felt to be inadequate, and with the ever-increasing demand for beds the difficulty in dealing with cases requiring and deserving hospital treatment has become greater in the last five years. That the governing boards of the various hospitals have risen to the situation is evident when one considers that within the last three years the Maternity Hospital has been rebuilt on a very large scale, the Cancer Hospital has been practically rebuilt, the Royal Samaritan Hospital for Women has been enlarged, the Western Infirmary has added a new block to its buildings, the Royal Infirmary is being entirely rebuilt on the same site, and the Royal Hospital for Sick Children is to be rebuilt immediately on a better site and with more than double its present accommodation. In the plans for the new Sick Children's Hospital arrangements have been made for a 300 cot hospital on a fine site extending over ten acres, but in the meantime it is intended to erect accommodation for about 200 cots. That means that it will be possible to treat 3000 children in the institution per annum as compared with 1000 in former years. The estimated cost, £120,000, will be exceeded, but the directors now have £102,000 in hand. The Royal Infirmary also is in process of reconstruction. The operations began in 1905, and in April, 1907, His Majesty King George, who was then Prince of Wales, laid the foundation stone. Since that time great progress has been made with the undertaking, but the new work is so much surrounded by the existing buildings, which have been retained as far as possible so that the bed accommodation may not be restricted during the present operations, that the passer-by gets only the vaguest idea of its nature and extent. The block at present being built is that for special diseases, together with the third section of the surgical block which will then be complete and will contain 290 beds. The new pathological block is also nearly completed, and it is the intention of the directors to proceed at an early date with the erection of a portion of the new medical block, which embraces nearly one-half of the main frontage upon Cathedral-square, together with the east wing which connects the Cathedral-square block with the central or special diseases block.

*Aberdeen Royal Infirmary and Lunatic Asylum.*

The annual general meeting of the corporation of the Royal Infirmary and Lunatic Asylum of Aberdeen was held in the infirmary hall on Feb. 8th, Lord Provost Wilson presiding. Mr. Peterkin, chairman of directors, in moving the adoption of the annual report, referred to the question of hospital abuse. He pointed out that those who improperly took advantage of the infirmary were not only unfairly taking gratuitous services from the physicians and surgeons, but were dishonestly using funds not subscribed for their benefit. A proposal to increase the infirmary directorate from 9 to 11, in order to allow of the inclusion of more working-class representatives, was defeated by a large majority.

*Open-air Recovery Schools: Aberdeen Medical Officer's Report.*

At a meeting of the school administration committee of the Aberdeen school board held on Feb. 6th a report by the medical officer, Dr. G. Rose, on open-air recovery schools was considered. Dr. Rose remarked that although theoretically such schools form an alluring and fascinating picture to the educationist, the philanthropist, and the school medical officer, when the scheme comes to be considered as part of the educational system difficulties arise. Such questions as—What class of children require treatment in open air, and what number, say, in a place like Aberdeen? What are the possibilities of providing such a school in a proper place? Is transit to the school possible and satisfactory? Would the cases most in need of treatment stand the fatigue of transit? Would the climatic conditions allow such schools to be conducted with benefit and success? Might not better results be got by different methods at a less cost? How may the relative value of the different factors acting on the child in the open air be estimated? May not a greatly diminished curriculum, an increase in number of meals, better quality of food, and mid-day sleep be factors as important as the massive stimulation of country air?—all these must be settled before a satisfactory answer can be given to the possibility of providing such a school. Dr. Rose treats the matter at greater length. With regard to suitable cases, cases of tuberculous lung disease are at once excluded on the ground of danger to the others; even those in the pre-tuberculous stage, though suitable for treatment, will not be available on account of the clinical impossibility of selecting them. If the same class were sent to the schools as are sent in Germany—namely, the backward children, who are physically debilitated, anæmic, &c.—and if the proportion of such children was the same in Aberdeen, sooner or later Aberdeen would have to provide for the outdoor education of 2500 or 3000 children. Site, buildings, transit, school-hours and food, education, cost, are all fully considered in the report.

*Elgin County Council and the Medical Inspection Question.*

The Elgin county council met on Feb. 6th, when there was submitted a minute of the joint meeting of the subcommittees of the county council and the secondary education committee, with regard to the terms they proposed for the joint appointment of a medical officer for the county and the inspection of schools. It may be stated that the county council proposes to pay £205, and the secondary education committee £245, the sum of £205 by the county council to include all expenses. After some discussion the recommendations of the subcommittees were adopted.

Feb. 14th.

# IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

*Infective Disease in Dublin.*

INFECTIVE disease in Dublin is arousing anxiety and putting a strain on hospital accommodation. Measles, whooping-cough, diphtheria, scarlet fever, and enteric fever are all present and increasing. Some six cases of each of the three last named are notified daily, while many cases apparently go without notification. Measles and whooping-cough are not notifiable in Dublin. Sir Charles Cameron, medical officer of health, has suggested milk as the distributer of typhoid and scarlatinal infection. On his advice most of the primary schools in the city have been closed. Should the outbreak continue steps will be necessary to provide hospital accommodation.

*Bequests to Dublin Hospitals.*

Last week the executors of the late Miss Augusta Magan applied to the Master of the Rolls for permission to hand over one-third part of her estate, some £20,000 to Sir Patrick Dun's Hospital and one-third to the Adelaide Hospital. This proposal was approved. The executors wished to apply the remaining third to the maintenance of a district nurse at Enfield, in the county Meath, or to devote it to the Meath Hospital, Dublin. The first alternative was declined, the consideration of the second postponed.

*Royal College of Surgeons Dinner.*

The annual dinner of the Royal College of Surgeons in Ireland was held on Feb. 11th in the hall of the College, Mr. R. H. Woods, the President, presided, and His Excellency the Lord Lieutenant of Ireland was the principal guest. The heads of the various colleges and professional bodies were also present in honour of the 127th anniversary of the granting of the College Charter. His Excellency, in his speech, referring to the death-rate from tuberculosis last year, said that in the Dublin registration area there had been a further drop of 0·1 since 1909—viz., from 3·8 per 1000 in 1909 to 3·7 in 1910, which he hoped indicated a permanent tendency to decrease. The decrease had been in the deaths from pulmonary tuberculosis. He urged the provision of some scheme to provide for children with surgical tuberculosis the advantages of sea air and good food.

*Public Health in Kingstown.*

The urban council of Kingstown has decided not to appoint a successor to the lately deceased superintendent medical officer of health, leaving to the dispensary medical officers the entire responsibility in future. A residential seaside district of 17,622, with a death-rate of 26·6 per 1000, seems to require more rather than less sanitary supervision.

*Outbreak of Enteric Fever in Lurgan.*

At the monthly meeting of the Lurgan urban council on Feb. 6th Dr. Samuel Agnew, medical officer of health, referred to a severe outbreak of enteric fever, between 30 and 40 cases having been transferred to the local hospital and two deaths having occurred, and intimated that the dissemination had occurred through a milk-supply contaminated, it was strongly suspected, by a typhoid carrier. The outbreak emphasised the necessity that existed for sanitary authorities enforcing strictly the regulations necessary for safeguarding milk-supplies. Dr. Agnew pointed out that as a large proportion of the milk-supply of Lurgan was brought in from the adjoining districts it behoved them not only to maintain a strict surveillance within their own district, but also to take cognisance of the manner in which the Dairies Order was carried out in their immediate neighbourhood. It appears the only power the urban council had over rural councils was to implore them to see after this work; and if they refused, to appeal to the Local Government Board, which could give them power over the dairies outside the town boundary, but that was a course they rarely appeared anxious to adopt. The clerk of the Lurgan urban council was instructed to ask the clerks of the Moira and Lurgan rural councils to enforce strenuously the power invested in them under the Dairies' Order and the Public Health Acts.

*Royal Sanitary Institute Congress.*

In connexion with the Congress of the Royal Sanitary Institute, which is to meet in Belfast from July 24th to 29th, under the patronage of the Lord Lieutenant, with Lord Dunleath as President, there are to be two sections: (1) Sanitary Science and Preventive Medicine, with Sir Lauder Brunton, Bart., as President; and (2) Engineering and Architecture, with Mr. W. K. Parry as President. The Lord Mayor of Belfast will preside over the conference of municipal representatives, and the Lady Mayoress over the conference of women on hygiene. The chairman of the public health committee, Dr. R. Thomson, will preside over the conference of port sanitary authorities; Sir Charles A. Cameron, C.B., over that of medical officers of health; Mr. P. C. Cowan, D.Sc., over that of engineers and surveyors; Mr. David Rutherford over that of sanitary inspectors; and Sir John Byers over that on the hygiene of childhood.

*A Novel Offer.*

On Feb. 11th, at the weekly meeting of the Coleraine board of guardians, a letter was read from Dr. James Steel, medical officer of Articlave dispensary district, proposing to appoint a trained general nurse altogether at his own expense, so that he should have the absolute control of her duties as well as the responsibility.

Feb. 14th.

# PARIS.

(FROM OUR OWN CORRESPONDENT.)

*The Technique of the Hypogastric Route.*

AT a meeting of the Society of Paris Surgeons, Dr. Paul Delbet presented a study in detail of the technique of the hypogastric route. He pointed out the disadvantages from his own point of view that attend inflation of the rectum, and showed the advantages of distension of the bladder with air and the importance of thus limiting the area of peritoneum in the field of operation. He recommended the practice of suturing the bladder wall to the skin from the very outset, so as to avoid infection of the space of Retzius. As to drainage, he always used Freyer's method. M. Delaunay said that to prevent the escape of liquid into the pre-vesical space he fixed the bladder with Kocher's forceps, thus at the same time limiting the extent of the incision. He allowed the bladder to empty itself through the urethra before incising it. M. Thévenard said that he employed a sound in the bladder to cut down upon, making it appear just above the pubes; he then seized the bladder walls with a couple of Doyen's mouse-toothed forceps, the fatty layers and the peritoneal *cul-de-sac* were then folded back and the walls incised layer by layer; the point of the sound being held in place immediately above the pubes and not pushed forward, it served as a guide.

*A Syndicate of Patients.*

In Ferté-Macé there has just been established a "syndicate of patients." The medical practitioners of this place recently raised their scale of fees. The patients, not recognising in the general rise of the cost of living any justification for the raising of medical fees, protested. The profession, however, took no notice of their protest, so the inhabitants formed a syndicate and decided to bring into Ferté-Macé one or more medical men who should agree to treat their patients at the old rate.

*Students of Dental Surgery.*

The students in dental surgery in Paris have appeared before the Chamber of Deputies with a petition setting forth the demands of their body. They claim, in view of the five years of study imposed, of the courses in the hospital and the dissecting-room, and the complete and difficult examinations they have to undergo for their diplomas, that they are entitled to the right of competing for State positions directly involving their specialty, and particularly for the post of surgeon-dentist of the hospitals. It is not a priority that they demand but an equality in their specialty with the medical men who alone at present are admitted to compete for the post of surgeon-dentist at the hospitals. Further, they demand that in the army surgeon-dentists shall have the relative rank of major and have the care of the mouths of the soldiers, in place of being the drudges of the service.

*Malta Fever and Mediterranean Fever.*

The Governor of Malta has complained to his Government regarding the name "Malta fever," the condition called by

this name being, he avers, wrongly so-called, for it implies that Malta is the only focus of the disease, and thus keeps up commercially a prejudice against the island. He requests that the name may be changed to "Mediterranean fever." The British Government communicated with the French Government on the matter, and the latter referred the question to the Academy of Medicine, which appointed a commission of investigation. The commission, through the report of M. Widal, by way of giving satisfaction to the Governor of Malta, makes the following observations: (1) The term "Malta fever" was given originally out of respect for the physicians of the island, who were the first to describe and study the disease; (2) the term "Mediterranean fever" would appear to be equally inapplicable, since the disease does not prevail throughout the Mediterranean.

*The Plague in China.*

A French physician, Dr. Menier, who was in charge of the Chinese Medical School at Tien-Tsin, being asked by the Chinese Government to undertake the fight against plague at Fondziadian, devoted himself to the task with entire self-abnegation. The disease, however, attacked him on the first day, and in spite of all the efforts of the Russian physicians, he died two days later, without allowing them to take his temperature for fear of transmitting the disease. Dr. Meslier, a deputy, is about to set out for Harbin to study the epidemic. Finally, Dr. Broquet, surgeon-major of the colonial troops, left Paris on Feb. 11th for the Far East. He is charged by the French Government with a double mission in the regions devastated by plague. He will first go to Tien-Tsin to institute all the sanitary measures possible for the safety of the French army of occupation, which numbers about a thousand at Tien-Tsin and at Peking. He will take with him 15,000 doses of the antiplague vaccine made by the Pasteur Institute, which has given excellent results in Indo-China. He will afterwards proceed to Manchuria to study the plague situation there.

*The Medical Orchestra.*

A few months ago there was established in Paris an association of physicians who are performers on various musical instruments. They form an orchestra of about 80 and meet several times a month for practice. Following on a first concert given last December, which was highly successful, they consented to give a second for the benefit of a medical foundation, the Maison du Médecin. The hall was too small to hold all the medical personages and the rest of the assembly that came to attend a function at once artistic and charitable. The concert consisted exclusively of pieces executed by doctors of medicine. The vocal part was rendered by a wife and a daughter of medical men, and the harp was played by a medical man's daughter who has already gained the first prize at the Conservatoire. Finally, Dr. Paul Mounet, an Associate of the Comédie Française, recited some beautiful verses by Dr. Montoya, while kinematographic pictures of the stomach and of frisky treponemata enlivened the interludes. The musical compositions of the President and Vice-President of the medical orchestra were warmly applauded.

Feb. 13th.

MEMORIAL TO THE LATE DR. J. M. RHODES.—It is not very often that a medical practitioner has his memory perpetuated by the building of a clock tower, but one erected as a memorial of the late Dr. John Milson Rhodes was unveiled at Didsbury about a fortnight ago. It stands in front of the railway station and bears an inscription, "A Friend of Humanity." He was known to the country at large as a pioneer of Poor-law reform, and his efforts in that direction extended over a period of 30 years. He did his work quietly, but with sound judgment and perfect mastery not only of the great principles but of the details of his subject. The Lord Mayor was invited to take over the memorial on behalf of the citizens of Manchester, and in the course of his remarks said that Dr. Rhodes would "be remembered ..... as the man who had brought about the reform of the workhouse dietary and the establishment of trained nursing service in the Poor-law" establishments. The sorrow at the death of Dr. Rhodes, which was felt in Didsbury, was widespread and genuine, for his sterling qualities had endeared him to the people.

# Obituary.

## ALFRED WILLIAM FREDERICK STREET, D.S.O.,

LIEUTENANT-COLONEL, I.M.S. (RETIRED).

THE news of the death, after only a few hours' illness, of Lieutenant-Colonel Street, D.S.O., will have come as a shock to a wide circle of friends both in India and in England. This event, which was due to cerebral hæmorrhage, occurring as it did without any premonition at the comparatively early age of 58, at his residence, Norsey Manor, Billericay, Essex, was wholly unexpected, as the deceased, a robust man, had always enjoyed good health. He had, in fact, been present in the hunting field on the Saturday preceding his death, which occurred on the morning of Monday, Jan. 30th.

Born in 1852, the eldest son of the late Rev. B. Street, vicar of Barnetby-le-Wold, Lincolnshire, Lieutenant-Colonel Street began his medical curriculum at St. George's Hospital in 1872. Here he succeeded in carrying off the Brackenbury prize of his year, and, qualifying in due course, he held for some little time a resident appointment at the Royal Free Hospital, Gray's Inn-road. Entering the Indian Medical Service in October, 1877, he served with distinction in the Afghan war of 1878–80, being present at the action of the Helmund on July 14th, 1880, the battle of Maiwand, defence of Kandahar, and the battle of Sept. 1st. For these he was mentioned in despatches and received the medal and clasp. In 1886–87 he took a very active part in the Burmese expedition, being again mentioned in despatches and receiving the Distinguished Service Order as well as the medal and clasp. The greater portion of his career in the Indian Medical Service was, however, passed in civil employ. In this he showed the same zeal and devotion to duty as was characteristic of him in his military work. From 1887 until his retirement with the rank of Lieutenant-Colonel in 1902, he held the position of Deputy Sanitary Commissioner under the Government of Bombay, in which he did very valuable service, both in the sanitary control of a very wide area and in the suppression of plague in Bombay itself.

Of a genial temperament, physically strong and active, a good horseman and fond of field sports, Lieutenant-Colonel Street made many friends. Modest and retiring, with a good deal of natural reserve, for he did not wear his heart on his sleeve, probably only those who knew him intimately really appreciated the depth and nobility of his character. A very high sense of duty actuated all his doings, and anything mean or petty was repugnant to him. The warmth of his affections, those who are privileged to speak knew well, as well as the strong undercurrent of religious belief which betrayed itself in his life.

Lieutenant-Colonel Street married in 1884 Helen, only daughter of the late Rev. E. M. Weigall, Vicar of Frodingham, Lincolnshire, for whom, as for his children (a son and three daughters), the greatest sympathy will be felt. The funeral took place at Barnetby, Lincolnshire, on Feb. 2nd, where the remains of the deceased were laid beside his father and mother near his old home. A memorial service held at the same hour at the parish church, Billericay, Essex, was largely attended, the fact testifying to the esteem with which he was regarded in the neighbourhood in which he had made his home for some years.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Sigmund Lustgarten of New York, who was formerly associated with Professor Kaposi, the eminent Vienna dermatologist. Dr. Lustgarten's name will be remembered in connexion with the supposed discovery of the bacillus of syphilis.—Dr. Alberto Severi, professor of forensic medicine in Genoa.—Dr. Kelsch, inspecting medical officer of the French army and member of the Paris Academy of Medicine.—Dr. Richard Stern, extraordinary professor of medicine and director of the Medical Department of the Polyclinic in Breslau. He refused the chair of medicine in the University of Greifswald. His chief work was "The Traumatic Origin of Internal Diseases." His death was due to influenza. He was 45 years of age.—Dr. Carl Parrot, an eminent Munich gynæcologist. He was a great authority on birds and was president of the Bavarian

Ornithological Society.—Dr. F. Fuchs, formerly extraordinary professor of electrotherapy in the University of Bonn.—Dr. Claude Martin of Lyons, corresponding member of the Paris Academy of Medicine.

# Medical News.

ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—At a meeting of the Comitia of the Royal College of Physicians of London on Jan. 26th, and of the Council of the Royal College of Surgeons of England on Feb. 9th, diplomas of L.R.C.P. and M.R.C.S. were conferred respectively on the following candidates (including one lady, Miss Pearl Jane Sproule, M.B., of Toronto University) who have passed the Final Examination in Medicine, Surgery, and Midwifery, of the Conjoint Examining Board in England, and have conformed to the bye-laws:—

Joseph Bamforth, Liverpool University; Albert Malcolm Barlow, London Hospital; Henry Cuthbert Bazett, B.A. Oxon., Oxford University and St. Thomas's Hospital; Thomas Beaton, University College, Cardiff, and Charing Cross Hospital; James Jamison Black, M.B., B.S. Melb., Melbourne University and Middlesex Hospital; William Percy Bonner, London Hospital; Thomas Rufus Bowen, University College, Cardiff, and London Hospital; George Francis Bradley, London Hospital; Thomas Wafer Byrne, Liverpool University; Wilfrid Thomas Chaning-Pearce, B.A. Cantab., Cambridge University and Guy's Hospital; Thomas Cock, Charing Cross Hospital; William Lewis Cowardin, St. Mary's Hospital; Heerajee Jehangir Manockjee Cursetjee, L.M.S. Bombay, Bombay and Cambridge Universities and London Hospital; Guy de Hoghton Dawson, Middlesex Hospital; Harold Dearden, B.A. Cantab., Cambridge and Manchester Universities and London Hospital; John Evan Dewar, M.D., C.M. McGill, McGill University, Middlesex Hospital, and Edinburgh; William James Edgar, St. Thomas's Hospital; Cyril Douglas Faulkner, St. Mary's Hospital; Hugo Flecker, M.B., Ch.M. Sydney, Sydney University and King's College Hospital; Arthur Duncan Gardner, B.A. Oxon., Oxford University and St. Thomas's Hospital; Alan Cecil Gemmell, M.A., LL.B. Cantab., Cambridge University and St. Thomas's Hospital; Leopold Sylvester Morrice Habich, B.A. Cantab., Cambridge University and St. Thomas's Hospital; Alan Ashton Henderson, University College Hospital; Thomas Brooke Hickley, Westminster Hospital; Guy Reginald Hind, Guy's Hospital; Gwilym James, B.A. Cantab., Cambridge University and University College Hospital; Heber Carss Jamieson, M.B. Toronto, Toronto University and London Hospital; Arthur Carveth Johnson, B.A. Cantab., Cambridge University and St. Thomas's Hospital; Thomas William James Johnson, M.B., Ch.B. Otago, Otago University and Middlesex Hospital; Robert Francis Jones, St. George's Hospital; George Arthur Edward Kelman, King's College and Westminster Hospital; Randal Young Kenny, M.B. Toronto, Toronto University, St. George's and St. Bartholomew's Hospitals; Charles Gordon Kirkpatrick, M.B. Toronto, Toronto University and Middlesex Hospital; William Balfour Laird, St. Thomas's Hospital; Harold Victor Lamb, Leeds University and Middlesex Hospital; Harold Drew Lander, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Peregrine Stephen Brackenbury Langton, Middlesex Hospital; Alexander Carson Clarke Lawrence, B.A. Cantab., Cambridge University and Middlesex Hospital; Basil Hugh Campbell Lea-Wilson, Cambridge University and St. Bartholomew's Hospital; Lewis Francis Gurslave Lewis, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; John Rhodes Liddell, Sheffield University; Samuel Marle, Bristol University; Octavius de Burgh Marsh, B.A. Cantab., Cambridge University and London Hospital; Ernest Percy Martin, St. Thomas's Hospital; Kalka Prasad Mathur, Punjab University and London Hospital; James William Edwin Mendis, L.M.S. Ceylon, Ceylon Medical College and Middlesex Hospital; John Morley, M.B., Ch.B. Manch., Manchester University; Michael Wellwood Morrison, Bristol University, Middlesex, St. Thomas's, and University College Hospitals; Nathan Mutch, B.A., B.C. Cantab., Cambridge University and Guy's Hospital; Alfred Philip Nicolle, London Hospital; Henry Locke Paddon, B.A. Oxon., Oxford University and St. Thomas's Hospital; Krishnan Gopinath Pandalai, M.B., M.S. Madras, Madras University and Middlesex Hospital; Hubert Charles George Pedler, University College Hospital; Cassius Affeleck Pereira, L.M.S. Ceylon, Ceylon Medical College and London Hospital; Albert Pfeiffer, L.D.S. Eng., Middlesex Hospital; Dudley Denham Pinnock, M.B., B.S. Melb., Melbourne University and Middlesex Hospital; James Powell, University College, Cardiff, and St. Mary's Hospital; Edward Prall, St. Thomas's Hospital; Thillustanum Sesha Soundara Rajan, Madras University and Middlesex Hospital; Henry Martin Rashbrook, London Hospital; William Alfred Reynolds, Bristol University; William Scarisbrick, B.Sc. Lond., Liverpool University; David Scurlock, St. Mary's Hospital; Francis Robert Bradley Skrimshire, St. Thomas's Hospital; Vere Edward Somerset, King's College Hospital; Pearl Jane Sproule (Miss), M.B. Toronto, Toronto University and Royal Free Hospital; Gerald Nicholson Stathers, Cambridge University and St. Bartholomew's Hospital; Berthold Somerville Taylor, M.A. Cantab., Cambridge University and St. George's Hospital; David Chester Thompson, M.D. Manitoba, Manitoba University and Middlesex Hospital; Alan Herapath Todd, B.Sc. Lond., Guy's Hospital; Stanley Van Someren Boyd, London Hospital; John Ernest Price Watts, Westminster Hospital; Frank Wells, St. Mary's Hospital; Esmond Tetley Willans, Cambridge and Leeds Universities; and Reginald Joseph Wooster, St. Mary's Hospital.

Diplomas in Public Health were conferred upon the following candidates (including two ladies, Miss C. A. King and Miss M. Thomson):—

Scott Campbell Adam, M.B., Ch.B. Glasg., Glasgow and Durham Universities; Claude John Eddowes Bennett, L.R.C.P., M.R.C.S., Westminster Hospital and King's College; Harold Boulton (Major I.M.S.), M.B., B.C. Cantab., L.R.C.P., M.R.C.S., Cambridge University, St. Bartholomew's Hospital, and Royal Army Medical College; Herbert Maughan Brown, M.D., Ch.B. Edin., Edinburgh University and Royal Institute of Public Health; Percy Norman Cave, M.B., B.Ch. Oxon., Oxford University, St. George's and St. Mary's Hospitals; Roderic Arthur Clapham, M.D., B.C. Cantab., L.R.C.P., M.R.C.S., Cambridge University and London Hospital; Alexander Dawson (Captain R.A.M.C.), M.B., Ch.B. Aberd., Aberdeen University and Royal Army Medical College; Kali Charan Dube, L.M.S. Punjab, Punjab University and University College; John Henry Jones, L.R.C.P., M.R.C.S., Guy's, Haslar, and King's College Hospitals; Charlotte Alice King (Miss), M.B., B.S. Lond., Royal Free and Middlesex Hospitals; James Fitzgerald Martin (Captain R.A.M.C.), M.B., Ch.B. Edin., Edinburgh University and Royal Army Medical College; Lawrence Pick, L.R.C.P., M.R.C.S., St. George's Hospital and Royal Institute of Public Health; Arthur Meurig Pryce, M.B., Ch.B. Edin., Edinburgh University and University College; Thomas Edwin Pryce, M.D., B.S. Lond., University College; Norman Emil Henry Scott (Captain I.M.S.), M.B., Ch.B. Glasg., Glasgow University and University College; Sidney Francis St. Germain Steadman, L.R.C.P., M.R.C.S., Charing Cross Hospital and University College; Sidney John Steward, M.D., B.C. Cantab., L.R.C.P., M.R.C.S., Cambridge University, St. Thomas's Hospital, and University College; Charles Henry Straton (Captain R.A.M.C.), L.R.C.P., M.R.C.S., St. Mary's Hospital and Royal Army Medical College; May Thomson (Miss), L.R.C.P. & S. Edin., L.F.P. & S. Glasg., Edinburgh School of Medicine for Women; Sydney Arthur Tucker, M.B., B.S. Lond., L.R.C.P., M.R.C.S., St. Bartholomew's Hospital and University College; and Charles Wilfred Vining, M.B., B.S. Lond., St. Mary's and St. George's Hospitals.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The Council on Feb. 9th conferred the following diplomas upon the undermentioned gentlemen, who have now complied with the by-laws:—

*F.R.C.S.*—Charles Henry Shorney Webb., M.B., B.S. Lond., M.R.C.S. L.R.C.P., Middlesex Hospital.

*L.D.S.*—Herbert Ferris Barge, Guy's Hospital; George Frederick Fawn, Bristol University; and Gordon Johnson, Charing Cross and Royal Dental Hospitals.

APOTHECARIES' HALL OF IRELAND.—At the Final Examination held recently the following candidates were successful:—

*Midwifery.*—J. L. Bocarrow, L. N. Denslow, H. Hutchinson, F. Muller-Fonseca, and Mrs. M. Neary.

*Medicine.*—Miss M. L. Batho, J. L. Bocarrow, Miss A. M. Headwards, and J. B. O'Donoghue.

*Surgery.*—Miss M. L. Batho, J. L. Bocarrow, Miss G. Ghosh, Miss A. M. Headwards, H. Hutchinson, G. M. Mayberry, and F. Muller-Fonseca.

*Completed Examination.*—Miss M. L. Batho, J. L. Bocarrow, Miss G. Ghosh, Miss A. M. Headwards, G. M. Mayberry, and F. Muller-Fonseca.

ST. MARK'S HOSPITAL FOR CANCER, FISTULA, AND OTHER DISEASES OF THE RECTUM, CITY-ROAD, E.C.—The Lord Mayor presided at this hospital on Feb. 9th at the annual general meeting of the governors. The report submitted and adopted referred to the provision during the past year of 11 new bedrooms for the accommodation of the nursing staff, and also to other alterations, including the erection of an outside fire-escape staircase. The income for the year had been £4642 and the expenditure £6972. There was therefore a very considerable need for an increase of contributions. King Edward's Fund had given £100 towards the ordinary work and £400 towards the structural alterations. It was felt that this was quite inadequate in view of the amount and value of the work done.

THE AFTER-CARE ASSOCIATION FOR THE RECOVERED INSANE.—The annual meeting of the After-Care Association for poor persons discharged recovered from asylums for the insane was held on Feb. 8th by the kind permission of Sir Victor and Lady Horsley, at 25, Cavendish-square, W., Mr. H. D. Greene, K.C., presiding over a large audience. The report, read by Mr. Roxby, stated that applications were received during 1910 on behalf of 379 cases, and the total income amounted to £1199 12*s.* 6*d.* The adoption of the report was moved by the Bishop of Barking, seconded by Dr. G. H. Savage, supported by the Master of the Temple and Dr. Robert Jones (Claybury Asylum). The re-election of vice-presidents, council, &c., was proposed by the Rev. H. R. Gamble, vicar of Holy Trinity, Chelsea, seconded by Dr. C. H. Bond (Long Grove Asylum) and supported by Dr. W. H. B. Stoddart (Bethlem Royal Hospital).

A vote of thanks to Sir Victor and Lady Horsley and to the chairman, proposed by Admiral de Courcy Hamilton and seconded by Dr. R. Percy Smith, to which the chairman suitably responded, terminated a most successful meeting.

ROYAL INSTITUTION OF GREAT BRITAIN.—The Friday evening discourse of Feb. 24th will be delivered by Professor Jean Perrin, at 9 o'clock at Albemarle-street, Piccadilly, W. The subject is Mouvement Brownien et Réalité Moléculaire (in French). On Tuesday, Feb. 21st, at 3 P.M., Dr. F. W. Mott, F.R.S., will deliver his sixth lecture on Heredity.

SURGICAL CONGRESS (BRUSSELS).—The Third Congress of the International Society of Surgery will take place at Brussels from Sept. 26th to 30th. The sessions of the society will be public, but only actual members will be able to take part in the discussions. Three main subjects will be considered—viz., Pleuro-pulmonary Surgery, reported by MM. Garré (Bonn), Gaudier (Lille), Girard (Geneva), Lenormand (Paris), Ferguson (Chicago), Van Stockum (Rotterdam), Sauerbruch (Marburg), Friedrich (Marburg); Colitis, reported by MM. Sonnenburg (Berlin), Segond (Paris), Gibson (New York), D'Arcy Power (London); Pancreatitis, reported by MM. Michel (Nancy), Korte (Berlin), Giordano (Venice). Full particulars may be obtained by addressing the Secretary-General of the Congress, M. le Professeur Depage, 75, Avenue Louise, Brussels.

DEATH OF MR. GERALD GEORGE HODGSON.—Deep regret was expressed at Brighton early in this month at the news of the death of Mr. Gerald George Hodgson, who, until a few years ago, was a well-known practitioner there. Latterly he had resided at Reigate, but did not have good health. He had been troubled with insomnia, and with the object of inducing sleep tired himself by taking a long walk to Hillingdon in Middlesex. Here he put up at a hotel and requested that he should not be called early. Next morning he was found dead, having succumbed to an overdose of morphine. At the inquest a verdict was returned that Mr. Hodgson died by misadventure. On the evening that Mr. Hodgson died his sister received a letter from him saying he was starting for Devonshire to recruit his health. Mr. Hodgson received his medical training at King's College Hospital and took the M.R.C.S. Eng. and L.S.A. diplomas in 1884.

THIRD INTERNATIONAL LARYNGO-RHINOLOGICAL CONGRESS, BERLIN.—This congress is announced to take place in Berlin from August 30th to Sept. 2nd under the presidency of Herr Geheimrat B. Fränkel. The following are the chief subjects for consideration: (1) The Relations of Experimental Phonetics to Laryngology, reported by Herr Gutzmann of Berlin and Herr Struyken of Breda; (2) Bronchoscopy and Œsophagoscopy, their Indications and Contra-indications, reported by Herr Killian of Freiburg, Herr Kahler of Vienna, and Dr. Jackson of Pittsburg; (3) The Lymphatic System of the Nose and of the Naso-pharynx, reported by Herr Broeckaert of Ghent, Sig. Poli of Genoa, and Mr. Logan Turner of Edinburgh; (4) The So-called Fibrous Naso-pharyngeal Polypus, reported by M. Jacques of Nancy and M. Hellat of St. Petersburg. Further particulars may be obtained from the secretary of the congress, Herr Professor Rosenberg, Schiffbauerdamm, 26, Berlin, N.W.

COLONIAL MEDICAL SERVICES.—*West African Medical Staff:* Mr. R. Cope, M.R.C.S. Eng., M.R.C.P. Lond., D.T.M. Liverp., medical officer, Gold Coast, has resigned his appointment; and Mr. E. J. Kelleher, L.R.C.S., L.R.C.P. Edin., L.F.P.S. Glasg., medical officer, Southern Nigeria, has retired temporarily on pension. The following gentlemen have been selected for appointment to the staff: Mr. A. J. Smith, M.B., Ch.B. Birm., Mr. W. G. Watt, M.B., Ch.B. Aberd., Mr. J. Donnelly, M.B., B.Ch. R.U.I., Mr. H. F. Hamilton, M.B., Ch.B. Edin., D.T.M. Liverp., Mr. P. D. Oakley, M.R.C.S. Eng., L.R.C.P. Lond., D.T.M. Liverp., and Mr. W. A. Ryan, L.R.C.P., L.R.C.S. (Gold Coast); Mr. G. Rollason, L.M.S.S.A. Lond. (Sierra Leone); Mr. E. L. Sieger, M.B., Ch.B. Glasg., D.T.M. Liverp., Mr. A. Hipwell, L.R.C.S., L.R.C.P. Irel., D.P.H. Liverp., D.T.M. Liverp.; and Mr. L. H. Booth, M.R.C.S. Eng., L.R.C.P. Lond. (Southern Nigeria). *Other Colonies and Protectorates:* Mr. F. L. Boag, M.B., Ch.B. Vict., has been selected for appointment as medical officer in the Gilbert and Ellice Islands Protectorate, and Mr. G. C. M. Davies, L.S.A. Lond., L.R.C.P. Edin., has been selected for appointment as a medical officer in the British Solomon Islands Protectorate.

LONDON COUNTY COUNCIL.—The London County Council has decided to extend the period of compulsory notification of cerebro-spinal meningitis for a further period of 12 months from March 13th, 1911. The first notification order came into force on March 12th, 1907. The Public Health Committee stated that considerable attention had been given to this disease in recent years in the principal cities of Europe and America, and it was important that in London the continuity of statistical information should be preserved.

PRESENTATIONS TO MEDICAL MEN.—Mr. Augustus William Dalby, L.R.C.P., L.R.C.S. Edin., of Frome, Somerset, has been presented with a cheque for £300 by the inhabitants of that town as a mark of respect and esteem, on the occasion of his leaving the district through ill-health.—On Feb. 4th at Winsford Mr. George Francis Sydenham, M.R.C.S. Eng., L.S.A., was presented with a cheque for £120 towards the cost of the purchase of a motor-car, together with an illuminated address. The presentation was given in commemoration of Mr. Sydenham's fiftieth birthday, and of his 25 years' service as medical officer for the first district and workhouse of the Dulverton (Somerset) Union.

SCHOOL CHILDREN'S HEALTH.—In his annual report Dr. J. W. Talent, the medical officer to the Ashton-under-Lyne education committee, gives some interesting information respecting the health of the elementary school children. During the year 2990 children were examined, of whom 592 suffered from various defects. At five years of age 40 per cent. had perfectly sound teeth, but there was a grievous falling off in the next few years, for at the age of 12 only 6 per cent. of the children had sound teeth. No doubt the quality of the food they are brought up on is one of the chief causes of this serious defect. Then, too, as to height and weight, these children of our factory system were found decidedly below normal. It should be noted, moreover, that this state of things existed, although nearly 60,000 free meals were provided at the school canteen for 800 children, at an average cost of 1·62 of a penny.

# Parliamentary Intelligence.

## NOTES ON CURRENT TOPICS.

*The New Parliament.*

THE new Parliament assembled on Jan. 31st, but certain time-honoured formalities had to be transacted before it could proceed with the business of the session. The Speaker had to be elected by the House of Commons and the oath had to be administered to Members. Then came the gracious speech from the Throne outlining the principal measures which the Government intends to submit to Parliament during the session. The motion for an address in reply to His Majesty's speech has afforded to the House of Commons the usual opportunity to pass in review the policy of the Cabinet. For these matters three weeks of Parliamentary time have been required. All the indications point to a session in large part devoted to the discussion of the controversial issues which have agitated recently the political life of the country. The Government will take for its business the time usually allotted to private members up to Easter. This will preclude the advancement in the early period of the session of all Bills not introduced by Ministers. Another effect of the Parliamentary situation may be to delay the introduction of departmental measures which have been expected for a long time. If any of them are introduced it is unlikely that reasonably rapid progress will be made with them.

*Departmental Reports.*

During the first few days of the session several reports of a departmental or statutory character have been presented to Parliament. The report on the work of the Central Midwives Board for the year ended March 31st, 1910, has been laid on the table of the House of Lords. A copy of the seventy-second Annual Report of the Registrar-General of Births, Deaths, and Marriages in England and Wales has been presented to the House of Commons. The ordinances of the Universities of Edinburgh and Glasgow in regard to the regulations for degrees in medicine have also been laid in compliance with statute. The Order made by the Local Government Board for Ireland agreeing to the institution of the office of dental surgeon to the workhouse of the Belfast Union has been notified in a similar manner.

*Asylum Officers (Employment, Pensions and Superannuation) Bill.*

A Bill "to limit the hours of employment of officers and servants in asylums, and to amend the Asylum Officers' Superannuation Act," has been introduced into the House of Commons by Viscount WOLMER and read a first time. In bringing it forward he has the support of Mr. SWIFT, Mr. KESWICK, Mr. POLLOCK, and Major STANLEY.

## HOUSE OF COMMONS.

WEDNESDAY, FEB. 8TH.

*The Use of Ehrlich's Preparation in the Army.*

Mr. GOLDMAN asked the Secretary of State for War whether the attention of the War Office had been drawn to the cures effected by the use of Professor Ehrlich's preparation "606"; and whether any steps had been taken to employ this preparation in suitable cases in the British army at home and abroad.—Mr. HALDANE forwarded the following written answer: Yes, sir. If the hon. Member will kindly refer to the *Journal of the Army Medical Corps* for November, 1910, and February, 1911, he will find accounts of cases in which the remedy has been tried.

THURSDAY, FEB. 9TH.

*The Irish Poor Law.*

Mr. LONSDALE asked the Chief Secretary to the Lord Lieutenant for Ireland when he intended to introduce his promised measure for the reform of the Irish Poor-law.—Mr. BIRRELL replied: I am afraid there is no chance of my introducing any such measure this session.

*Irish Butter Legislation.*

Mr. H. BARRIE asked the Chief Secretary to the Lord Lieutenant for Ireland when it was proposed to introduce the Butter Bill promoted by the Agricultural and Technical Department.—Mr. BIRRELL said in reply: I am afraid that there will be no room for a Butter Bill in this session.

*Irish Medical Practitioners and the Motor Spirit Duty.*

Mr. GINNELL asked the Secretary to the Treasury why the rebate of motor spirit duty to which medical practitioners were entitled under the Finance (1909-10) Act, 1910, had not yet been paid in Ireland in respect of 1909 or 1910 in cases in which the claim had been duly made, accompanied by vouchers; whether to entitle them to the rebate medical practitioners were required to prove that manufacturer and dealer had also paid the duty, and furnished with power to obtain this information; and when would the rebate due in respect of the last two years be paid to those gentlemen.—Mr. HOBHOUSE replied: If the honourable gentleman will furnish the Commissioners of Customs and Excise with the names and addresses of any medical practitioners in Ireland who have claimed but have not been paid the rebate inquiry will be made into the circumstances in each instance. Medical practitioners and other claimants for rebate are not required to prove that manufacturers of and dealers in motor spirit have paid the duty. The inquiries as to the validity of the vouchers or certificates attached to the claims are made by officers of Customs and Excise.

MONDAY, FEB. 13TH.

*The Plague and Chinese Pork.*

Mr. FELL asked the President of the Local Government Board whether during the continuance of the virulent plague in China he could totally prohibit the introduction of Chinese pork into this country, having regard to the reports of the disposal of the dead bodies there and the reported habits of the Chinese pigs.—Mr. BURNS replied: The districts in China which are affected with plague are remote from the districts from which pigs have been imported to this country. No circumstances have arisen necessitating the taking of other measures than those of adequate inspection of imported meat, and this is in operation.

*Imports of Chinese Pork.*

Mr. FELL asked the President of the Local Government Board whether the shipments of Chinese pork were increasing to this country; whether over 24,000 carcasses arrived at Liverpool from China last year; whether every one of these carcasses was examined; and how many were passed as free from disease and how many were rejected.—Mr. BURNS answered: Fewer carcasses were imported during 1909 than during 1910, but, as the importations of Chinese pork did not commence until July of the former year, I should hesitate to say whether the shipments are increasing. I understand that 23,246 carcasses were received at Liverpool during last year, and that the whole of these were examined. Of this number 343 were condemned on account of unsoundness which developed in transit and 352 on account of disease or abnormal condition.

*The Poisons and Pharmacy Act.*

Captain CRAIG asked the Secretary of State for the Home Department whether by-laws had yet been made by the Pharmaceutical Society under the Poisons and Pharmacy Act, 1908, Section 4 (b).—Mr. CHURCHILL replied: I am informed that before formulating any by-laws under Section 4 (b) of the Poisons and Pharmacy Act, 1908, the Pharmaceutical Society of Great Britain has to dispose of certain preliminary questions connected with the educational curriculum of pharmaceutical chemists and of chemists and druggists, and that the society is now actively engaged on these questions.

*European Medical Men in the Plague Area.*

Mr. ALLAN BAKER asked the Under-Secretary of State for Foreign Affairs whether he could say what precautions were being taken by the Chinese Government to ensure the safety of European medical men working in the plague district of Harbin.—Mr. MCKINNON WOOD wrote in reply: His Majesty's Minister at Pekin reports that all the medical men have been inoculated with Haffkine's vaccine. They are comfortably installed in a railway car, with the exception of one who is living with the British Consul. The Chinese Government has done its utmost for the personal comfort of the medical men, whose private letters show appreciation of their considerate treatment. They wear masks, oilskin boots, and complete overalls when dealing with cases of plague. The French doctor, Mesny, who was not inoculated, became infected owing to a patient coughing in his face while examining him unmasked. Dr. Jackson, the British medical man, died after continuous hard work among a crowd of infected coolies. It is believed that he was too exhausted to maintain proper precautions. The heroism of the doctors, Sir John Jordan reports, is beyond praise.

*The Medical Inspection of School Children.*

In the course of the debate on the Address when an amendment having reference to the burdens on local rates was under discussion,

Mr. RUNCIMAN (President of the Board of Education) said: I come to the purely administrative case in which the Government is charged with having been unjust to the Local Government ratepayers. As to the Act passed for the feeding of school children, I think it will be agreed, except by a very small majority, that it has not imposed a very heavy burden. The Act providing for the medical inspection of school children has no doubt involved London in a very large expenditure. We have been overhauling the method by which the London County Council has provided for the medical inspection of school children, and we could not pronounce it efficient. When an honourable Member refers to this medical treatment and suggests that we have tried to convert what is an optional into a compulsory measure, I reply that we have done nothing of the kind. We have made it perfectly clear that the Act is optional and that we are only carrying out our statutory duty to see that the arrangements which are made are sanctioned by the Board of Education. We cannot sanction schemes of medical treatment which are not efficient and do not cover the ground, but in many cases leave the whole question of the medical inspection of school children in a worse position for the future than it has been in the past.

TUESDAY, FEB. 14TH.

*The Adulteration of Bread.*

Mr. BOTTOMLEY asked the President of the Local Government Board whether his attention had been called to the adulteration of bread by means of the treatment of flour with acid phosphate of calcium, derived from the action of sulphuric acid on bones; and, if so, whether he would consider the desirableness of taking measures to stop the practice.—Mr. BURNS replied: My attention has been called to this matter and some time ago I directed an inquiry to be made regarding it. The report on this inquiry is now in preparation.

Mr. GOLDMAN asked whether in the light of the recent agitation for a standard in bread he proposed any legislative standards for bread and other foodstuffs.—Mr. BURNS said in reply: The question of the comparative nutritive values of bread made from various classes of flour is now being investigated by the Foods Department of the Local Government Board, and at present I am not prepared to express an opinion on the question of standards.

*Rats and the Plague.*

Captain CLAY asked the President of the Local Government Board whether the Government was prepared to introduce legislation authorising local authorities to take such measures as might be necessary within their area for the destruction of rats in order to minimise the danger of an epidemic of plague.—Mr. BURNS answered: In November of last year I issued an Order directing the local authority of any district in which rats were infected or threatened with plague, or in which there was an unusual mortality among rats, to take measures for the destruction of rats and for preventing their entrance into buildings. Further legislation for this purpose does not at present appear to be required.

*Milk Legislation.*

Mr. GOLDMAN asked the President of the Local Government Board whether the Government proposed to introduce the Dairies Bill this session as a first-class measure.—Mr. BURNS replied: I am not at present in a position to make any announcement on this subject.

WEDNESDAY, FEB. 15TH.

*The Ingredients of Patent Medicines.*

Mr. STEPHEN COLLINS asked the Secretary of State for the Home Department whether he was prepared to give effect to the view

favoured by his predecessor at the Home Office and appoint a Select Committee to consider the advisability of issuing regulations making it compulsory upon all manufacturers of medicines liable to patent medicine duty to print on the label of the bottle or other vessel in which such was sold the full ingredients of such bottles or vessels, as well as the diseases which they purported to cure.—Mr. CHURCHILL wrote in reply: I am making inquiries and will inform my honourable friend in due course.

# Appointments.

*Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to* THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

AWDRY, ARTHUR JOHN, L.R.C.P. Lond., M.R.C.S., has been appointed Honorary Medical Officer to the Berkeley (Gloucestershire) Hospital.

AWDRY, WALTER ROBERT, M.B. Durh., M.R.C.S., has been appointed Honorary Medical Officer to the Berkeley (Gloucestershire) Hospital.

BANKS, J., M.B., M.S. Glasg., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Dunoon District of the county of Argyll.

BRODRICK, CHARLES CUMBERLAND, L.R.C.P., L.R.C.S., L.M. Edin., has been appointed Medical Officer for the Whitchurch and South Lydford District of the Tavistock (Devon) Board of Guardians.

BURNET, ROBERT, M.Sc., M.B., B.Ch. Vict., M.Sc., M.B., B.Ch. Liverp., D.P.H. Birm., has been appointed Medical Officer of Health for the County of Cornwall.

BYWATER, E. F. W., M.R.C.S., L.R.C.P. Lond., has been appointed Medical Officer of Health for Withington, Manchester.

COOPER, CHARLES EDWARD, M.B., B.C. Cantab., has been appointed Medical Officer of Health for the Ivybridge (Devon) Urban District Council.

DOWSETT, ERNEST B., M.R.C.S., L.R.C.P. Lond., L.D.S., has been appointed Assistant Dental Surgeon to Guy's Hospital.

GARMAN, W. C., M.B., M.S. Edin., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Wednesbury District of the county of Stafford.

HALL, I. WALKER, M.D. Vict., Professor of Pathology in the University of Bristol, has been appointed External Examiner in that subject at the University of Manchester.

MOISER, L. H., M.B. Lond., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Crediton District of the county of Devon.

PATTISON, C. R. M., L.R.C.P. & S. Irel., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Ballyward District of the county of Down.

PEARCE, FRANK J., L.D.S. R.C.S., has been appointed Assistant Dental Surgeon to Guy's Hospital.

RUTHERFOORD, H. E., M.D., B.Ch. Dub., has been appointed Honorary Assistant Physician to the Chester General Infirmary.

WATSON, ANNE M., L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer to the Morningfield Hospital, Aberdeen.

# Vacancies.

*For further information regarding each vacancy reference should be made to the advertisement (see Index).*

ASHTON-UNDER-LYNE UNION WORKHOUSE.—Assistant Medical Officer. Salary £150 per annum, with rations, laundry, and residence.

BIRMINGHAM AND MIDLAND HOSPITAL FOR SKIN AND URINARY DISEASES.—Clinical Assistant for three months. Salary at rate of 52 guineas per annum.

BOLTON INFIRMARY AND DISPENSARY.—Third House Surgeon. Salary £90 per annum, with apartments, board, and attendance.

BOOTLE BOROUGH HOSPITAL.—Junior House Surgeon. Salary £80 per annum, with residence, board, and laundry.

BRISTOL, UNIVERSITY OF.—Demonstrator of Physiology. Salary £180 per annum.

CHELSEA HOSPITAL FOR WOMEN, Fulham-road, S.W.—Clinical Assistant for three months.

CLAPHAM MATERNITY HOSPITAL, Jeffreys-road.—Two House Surgeons (females) for six months.

CROYDON, COUNTY BOROUGH OF.—Assistant Medical Officer. Salary £250 per annum.

DUMFRIES, COUNTY AND BURGHS OF.—Medical Assistant to Medical Officer of Health and School Medical Officer. Salary £250 per annum.

EDINBURGH ROYAL INFIRMARY.—Superintendent. Salary £600 per annum, with house, coal, and light.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark Bridge-road, London, S.E.—House Physician for six months. Salary at rate of £60 per annum, with board, residence, and washing.

FARRINGDON GENERAL DISPENSARY AND LYING-IN CHARITY, 17, Bartlett's Buildings, Holborn-circus, E.C.—Resident Medical Officer. Salary £100 per annum, with rooms, attendance, fire, &c. Also Honorary Dental Surgeon.

GATESHEAD UNION WORKHOUSE.—Resident Medical Officer. Salary £250 per annum, with apartments, rations, and washing.

GLOUCESTER COUNTY ASYLUMS, Wotton, Gloucester.—Junior Assistant Medical Officer, unmarried. Salary £150 per annum, with apartments, board, washing, &c.

GREAT YARMOUTH HOSPITAL.—House Surgeon, unmarried. Salary £100 per annum, with board, lodging, and washing.

HAMPSTEAD GENERAL AND NORTH-WEST LONDON HOSPITALS.—Surgeon to Out-patients.

HORNSEY, BOROUGH OF.—Assistant Medical Officer of Health, Assistant to Medical Superintendent of Borough Isolation Hospital, and Assistant School Medical Officer, unmarried. Salary £225 a year, with rooms and board.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.—Anæsthetist. Salary £15 15s. per annum.

KENSINGTON DISPENSARY AND CHILDREN'S HOSPITAL.—Vacancy on Honorary Medical Staff.

LEAMINGTON, WARNEFORD, LEAMINGTON, AND SOUTH WARWICKSHIRE GENERAL HOSPITAL.—Junior Resident Medical Officer. Salary £65 per annum, with board, washing, and apartments.

LIVERPOOL, DAVID LEWIS NORTHERN HOSPITAL.—Three House Surgeons for six months. Salaries at rate of £60 per annum, with residence and maintenance.

LIVERPOOL, ROYAL SOUTHERN HOSPITAL.—Three House Surgeons and Two House Physicians for six months. Salary at rate of £60 per annum, with board and residence.

LLANYBYTHER, CARMARTHENSHIRE, WEST WALES SANATORIUM.—Medical Superintendent. Salary £250 per annum, with board and residence.

MANCHESTER CHILDREN'S HOSPITAL, Pendlebury, near Manchester.—Resident Medical Officer, unmarried. Salary £90 per annum.

MANCHESTER HOSPITAL FOR CONSUMPTION AND DISEASES OF THE THROAT AND CHEST, Hardman-street.—Assistant Medical Officer and Pathologist. Salary £60 per annum.

MANCHESTER ROYAL INFIRMARY.—House Physicians and House Surgeons, unmarried, for six months. Board and residence provided.

METROPOLITAN HOSPITAL, Kingsland-road, N.E.—House Physician and Two House Surgeons. Salaries at rate of £60 per annum. Also Assistant House Physician, and Two Assistant House Surgeons. Salaries at rate of £40 per annum. Board and washing in each case. All for six months.

NEWCASTLE-UPON-TYNE, UNIVERSITY OF DURHAM COLLEGE OF MEDICINE.—Lecturer on Public Health.

NEW HOSPITAL FOR WOMEN, Euston-road.—Senior Assistant (female) in Out-patient Department.

NEWPORT AND MONMOUTHSHIRE HOSPITAL.—House Surgeon. Salary £60 per annum, with board, residence, and laundry.

NOTTINGHAM WORKHOUSE INFIRMARY.—Assistant Resident Medical Officer, unmarried. Salary £130 per annum, with apartments, board, washing, and attendance.

PLYMOUTH, SOUTH DEVON AND EAST CORNWALL HOSPITAL.—Honorary Anæsthetist.

RANSOM SANATORIUM FOR CONSUMPTIVES, Sherwood Forest, near Mansfield, Notts.—Resident Medical Officer (female). Salary £100 per annum, with board, residence, and washing.

ROYAL NAVAL MEDICAL SERVICE.—Twelve Commissions.

ROYAL SOUTH HANTS AND SOUTHAMPTON HOSPITAL.—House Surgeon. Salary £100 per annum, with rooms, board and washing.

ST. MARY'S HOSPITAL MEDICAL SCHOOL, Paddington, W.—Lecturer on Anatomy. Salary at rate of £350 per annum.

ST. PANCRAS AND NORTHERN DISPENSARY, 126, Euston-road.—Resident Medical Officer, unmarried. Salary £105 per annum, with residence, attendance, and midwifery fees.

ST. PETER'S HOSPITAL FOR STONE, &c., Henrietta-street, Covent Garden, W.C.—Junior House Surgeon for six months. Salary at rate of £50 per annum, with board, lodging, and washing.

SCARBOROUGH HOSPITAL AND DISPENSARY.—Junior House Surgeon. Salary £80 per annum, with board, residence, &c.

SHREWSBURY, SALOP INFIRMARY.—House Physician. Salary at rate of £70 per annum, with board and apartments.

SOUTHPORT INFIRMARY.—Resident Junior House and Visiting Surgeon, unmarried, for six months. Salary £70 per annum, with residence, board, and washing.

STOCKPORT INFIRMARY.—Junior House Surgeon. Salary £80 per annum, with board, washing, and residence.

SUNDERLAND INFIRMARY.—Two House Surgeons. Salary £80 per annum, with board, residence, and washing.

TOWER HAMLETS DISPENSARY, Whitehorse-street, Stepney, E.—Resident Medical Officer. Salary £100 per annum, with apartments, washing, light, and attendance.

TRURO, ROYAL CORNWALL INFIRMARY.—House Surgeon, unmarried. Salary £100 per annum, with rooms, board, and washing.

WAKEFIELD, WEST RIDING ASYLUM.—Assistant Medical Officer. Salary £140 per annum, with apartments, board, washing, and attendance.

WEST BROMWICH DISTRICT HOSPITAL.—Assistant Resident House Surgeon, unmarried. Salary £75 per annum, with board, residence, and washing.

WEST LONDON HOSPITAL, Hammersmith-road, W.—Two House Physicians and Three House Surgeons for six months. Board, lodging, and laundry allowance provided.

WINCHESTER, ROYAL HAMPSHIRE COUNTY HOSPITAL.—House Physician.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of a vacancy as Certifying Surgeon under the Factory and Workshop Act at Glasgow, in the county of Lanark.

# Births, Marriages, and Deaths.

## BIRTHS.

BEATH.—On Feb. 7th, at Barnard House, Bath, the wife of David Leslie Beath, M.R.C.S., L.R.C.P., of a daughter.

CARMODY.—On Feb. 8th, at "Mayaro," Tilehurst, Berks, the wife of Ernest P. Carmody, M.R.C.S., L.R.C.P., of a son.

DRUITT.—On Feb. 10th, at Parkfields, Alvaston, the wife of Claud Francis Druitt, M.R.C.S., L.R.C.P., of a daughter.

## DEATHS.

CRAWFORD.—On Feb. 7th, at 40, Rodney-street, Liverpool, in his 75th year, Joseph Dawson Crawford, M.D., F.R.C.S. Edin., formerly Senior Surgeon to the Liverpool Hospital for Cancer and Skin Diseases. Interred at Smithdown-road Cemetery, Liverpool, on Feb. 11th. (Friends will kindly accept this, the only, intimation.)

HORLEY.—On Feb. 7th, at St. Catherine's-terrace, Hove, William Lewis Horley, M.R.C.S., L.S.A., in his 85th year.

*N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

# Notes, Short Comments, and Answers to Correspondents.

## ENCEINTE.

*To the Editor of* THE LANCET.

SIR,—In reply to Dr. Cordes, I quite recognise that we must always hold in due reverence the opinions of established authorities, but at the same time it is possible while doing so to retain a certain amount of healthy doubt about some of their rulings, otherwise errors and imperfections would remain and advance be rendered impossible. There have been many disputed etymologies, and what passed muster a century ago in this respect will not do so to-day always. Ménage died in 1692, which is a long time ago. Scheler only died in 1890. Littré died in 1881, and was succeeded by Brachet, whose work is well known and highly appreciated. Of the old etymologists it could be said of more than one of their explanations, "*Se non è vero, è ben trovato.*" Dr. Meissner, in his "Philology of the French Language," said that Ménage deliberately invented certain words which never existed in order to explain some of his etymology. I will cite Bescherelle upon the word "*Enceindre.*" He says, "étymologie, lat., in, *dans*; cingere, *ceindre, entourer*," and he says that "Enceint, enceinte," are "part. pass. du verbe Enceindre. S'empl. adjectiv. Entouré," and immediately following he gives as an example "*Femme enceinte.*" The past participle cannot surely differ in etymology from the infinitive of the verb. Bescherelle did not have a high opinion of some of the authorities quoted by Dr. Cordes, which fact he states in his preface. It will be noted that Bescherelle considered the Latin "In" in this connexion to mean "Dans." The example usually given of the opposite is the French word "ennemi" from the Latin *inimicus*, but "en" in French nearly always means "in" or "away." The latter sense is seen in "envoyer" from old French "entvoyer," Low Latin, *inde-viare*. The privative Latin "In" is nearly always "In" in French.

The Latin had the following words for "ungirt" or "loosely attired"—viz., "Discinctus" and "Recinctus." From the first named was derived the French "Dessanglé," meaning "ungirt." The English language also has "Ingirt" and "Engirt," but we do not accept the prefixes "in" and "en" as being privative. We use the word "Ungirt," the "Un" being the strong privative prefix used with participles.

Regarding the objection by Dr. Cordes that "it is not the lady who is cloistered but the child," I purposely said in my previous letter, "If we had retained and *shortened* the old expression." To illustrate this better I will quote the following expression from Spenser's "Faerie Queene," viz., "Me then he left enwombed of this child." In oblique narration, "She was then left enwombed of that child by him," and as cloister was a synonym for "womb" it could have been said, "She was then left encloistered" (or "cloistered"), the words "of the child" being understood. These old expressions are sometimes puzzling. For instance, the expression "she was delivered of a child" could be taken in two senses, but one is guided by common knowledge in interpreting what is meant. There is a striking line in the Bible which says, "A woman shall compass a man" ("encompass" in the Revised Version). This is stated by authorities to mean, "A virgin shall conceive a male child." The word compass here is surely used in the sense of "*entourer*," to enclose, or surround. The French is "La femme environnera l'homme" and the Spanish "El hembra rodeará al varon." There is a Spanish word for pregnant which is significant. It is "embarazada" which also means "embarrassed," i.e., "barred in." The ultimate authority of several French etymologists for "incincta" is Isidore of Seville (or Isidorus Hispalensis) who died in 636 A.D. It would not be difficult to make out a plausible case for "in sinus" or "insinuatus." The word "sein" in French is derived from sinus, and there is an obsolete law term "enseint" meaning pregnant.

The following first three stanzas of "Childe Waters," from Percy's Reliques of Ancient English Poetry, may be of interest:—

> "Childe Waters in his stable stoode,
> And stroakt his milke-white steede;
> To him a fayre yonge ladye came
> As ever ware woman's weede.
>
> Sayes, Christ you save, good Childe Waters;
> Sayes, Christ you save, and see:
> My girdle of gold that was too longe,
> Is now too short for mee.
>
> And all is with one chyld of yours,
> I feele sturre att my side:
> My gowne of greene it is too straighte;
> Before, it was too wide."

The lady, I take it, has not abandoned her girdle, but in the circumstances would have liked it rather longer.

I am, Sir, yours faithfully,

Feb. 11th, 1911. BLANCUS.

## A NEW PRIMARY BATTERY.

WE have recently had an opportunity of testing the Silvertown Bleeck-Love primary battery and the results were quite satisfactory. It is a two-fluid cell consisting of a porous pot holding the excitant and zinc and an outer vessel of glass or other material containing the depolariser in which the negative plate—a perforated carbon cylinder—is immersed. The obvious advantages of the cell are that it has a remarkably high E.M.F., low internal resistance, great current capacity, and, as we ourselves have found, a constant and steady output. The zinc consumption is small. Two cells on one charge will, it is stated, run a 7-inch fan for 36 hours, or a 4-volt 4-c.p. lamp for 18 hours, or will charge a 20-ampère-hour 4-volt accumulator in 16 hours. The number of applications to which this cell may usefully be put barely needs pointing out, but mention may be made in these columns of X ray and surgical work. The cell was submitted to us by the Indiarubber, Gutta Percha, and Telegraph Works Company, Limited, of Silvertown and 106, Cannon-street, London, E.C.

## "MERCK'S INDEX."

THE third edition of "Merck's Index" has been published, and copies may be obtained at the London office, 16, Jewry-street, E.C. It is a wide and comprehensive work of reference on materia medica, pharmacology, and pharmacy, and the subject-matter is brought into line with the advances made up to the end of May, 1910.

## "ROUNDED-OFF" ATOMIC WEIGHTS.

THE atomic weights of elements employed in the pharmacopœias of different nations show considerable variation in magnitude, particularly with regard to the first, second, and third place of decimals. In the opinion of Mr. W. H. Martindale, Ph.D., who read a paper on the subject at an evening meeting of the Pharmaceutical Society on Feb. 7th, it might be better to do away with the decimal proportions, excepting perhaps in the case of chlorine, copper, and st[illegible]ntium. Such a series of rounded-off figures would be sufficiently accurate for pharmaceutical work, and Mr. Martindale suggests that the matter might be considered in connexion with the revision of the British Pharmacopœia.

*E. T.*—A paraffin stove which gives off an offensive fume or smell is obviously a source of disturbance to the health.

**COMMUNICATIONS not noticed in our present issue will receive attention in our next.**

## A DIARY OF CONGRESSES.

WE shall publish this diary from time to time that our readers may have under their hands the dates of the approaching scientific Congresses. It is unnecessary to issue the lists of all these functions week by week, and we propose to make only such gatherings as will occur in the immediate future the subject of regular announcement. The following Congresses, Conferences, and Exhibitions are announced for February, March, and April, 1911:—

Feb. 20th–25th (Cairo).—Fifth International Congress for the Blind.
March 2nd–6th (Berlin).—Thirty-second Balneological Congress.
" 23rd (Paris).—First Congress of French Medical Journalists.
" 28th–April 25th (Tunis).—Exhibition of Hygiene.
April 4th–7th (London).—Fourth Annual Nursing and Midwifery Conference and Exhibition.
" 18th–20th (Paris).—Third Congress of Physiotherapy of French-speaking Physicians.
" 18th (Berlin).—Tenth Congress of the German Orthopædic Surgery Society.
" 19th–22nd (Berlin).—German Surgical Congress. (Fortieth Annual Meeting.)
" 19th–22nd (Wiesbaden).—Twenty-eighth German Congress of Internal Medicine.
" 20th–22nd (Groningen).—Thirteenth Nature and Medical Congress.

**The following journals, magazines, &c., have been received:**—The Selborne Magazine, Il Morgagni, Rivista Ospedaliera, La Presse Médicale d'Egypte, Pioneer Mail, Bulletins et Mémoires de la Société Médicale des Hôpitaux de Paris, Le Progrès Médical, Archives de Médecine et de Pharmacie Militaires, Indian Public Health, Transactions of the Society of Tropical Medicine and Hygiene, Indian Medical Gazette, Indian Engineering, Archives of the Roentgen Ray, Gazette Médicale de Paris, The Middlesex Hospital Journal, Liverpool Medico-Chirurgical Journal, Review of Neurology and Psychiatry, Philippine Journal of Science, Die Therapie der Gegenwart, La Semana Medica, Bulletin de l'Académie de Médecine, The Clinical Journal, St. George's Hospital Gazette, National Health, Journal of Laryngology, Rhinology, and Otology, American Journal of Medical Sciences, Detroit Medical Journal, Archives of Internal Medicine, Engineer, Scientific American, Tuberculosis, La Presse Médicale Belge, Gazzetta degli Ospedali, Gazette des Sciences Médicales de Bordeaux, Revue de Médecine, Revue de Chirurgie, La Clinique Ophtalmologique, Bulletins et Mémoires de la Société de Radiologie Médicale de Paris, Paris Médical, Revue Française de Médecine et Chirurgie, Monthly Cyclopædia, Allgemeine Medizinische Central-Zeitung, Cadiz Medico, International Journal of Surgery, L'Hygiene de la Viande et du Lait, La Policlinique, The Public Health Journal of Canada, The Official Gazette of the United States Patent Office,

Journal of the Royal Institute of Public Health, Local Government Chronicle, Midland Medical Journal, Maryland Medical Journal, The Cleveland Medical Journal, The Boston Medical and Surgical Journal, New York Medical Journal, Journal of the American Medical Association, Army and Navy Gazette.

# Medical Diary for the ensuing Week.

## SOCIETIES.

**ROYAL SOCIETY OF MEDICINE, 15, Cavendish-square, W. (temporary address during building of new house).**

TUESDAY.

THERAPEUTICAL AND PHARMACOLOGICAL SECTION (Hon. Secretaries—H. Charles Cameron, H. H. Dale): at 4.30 P.M.

Dr. A. P. Beddard: Some Points in the Treatment of Lobar Pneumonia.

Mr. F. R. Smyth: The Use of Local Anæsthetics in the Mouth.

(Members of the Odontological Section and Section of Anæsthetics are invited to take part in the Discussion.)

PATHOLOGICAL SECTION (Hon. Secretaries—C. Bolton, J. C. G. Ledingham): at 8.30 P.M.

Dr. A. G. Levy: Asphyxia under Chloroform.

Dr. B. H. Wedd: Multiple Submucous Tumours in the Small Intestine associated with Carcinoma of the Larynx.

Mr. S. G. Shattock: Lamarckism and Callosities.

Dr. A. E. Boycott: Uterine Tumours in Rabbits.

FRIDAY.

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic (2 P.M.) Hospitals operations are performed daily.

## EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.*

*Lectures, original articles, and reports should be written on one side of the paper only,* AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

*Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.*

*We cannot prescribe or recommend practitioners.*

*Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."*

*Letters relating to the publication, sale and advertising departments of* THE LANCET *should be addressed "To the Manager."*

*We cannot undertake to return MSS. not used.*

## MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

The Index and Title-page to Vol. II. of 1910 were given in THE LANCET of Dec. 31st, 1910.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1910 are now ready. Bound in cloth, gilt lettered, price 16*s.*, carriage extra.

Cases for binding the half-year's numbers are now ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

### TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

| FOR THE UNITED KINGDOM. | | TO THE COLONIES AND ABROAD. | |
|---|---|---|---|
| One Year ... ... ... | £1 1 0 | One Year ... ... ... | £1 5 0 |
| Six Months ... ... ... | 0 12 6 | Six Months ... ... ... | 0 14 0 |
| Three Months ... ... | 0 6 6 | Three Months ... ... | 0 7 0 |

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rate of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

### TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at these rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

# Hunterian Lecture

ON

# THE IMMUNITY REACTION IN DIAGNOSIS, ESPECIALLY OF TUBERCULOSIS AND SYPHILIS.

*Delivered in the Theatre of the Royal College of Surgeons of England on Feb. 6th and 8th, 1911,*

BY W. D'ESTE EMERY, M.D., B.Sc. LOND., M.R.C.S. ENG.,

PATHOLOGIST AND LECTURER ON PATHOLOGY AND BACTERIOLOGY AT KING'S COLLEGE HOSPITAL.

## LECTURE I.

*Delivered on Feb. 6th.*

## TUBERCULOSIS.

MR. PRESIDENT AND GENTLEMEN,—By the term "immunity reaction" I refer to the series of specific changes that occur when any infective agent attacks the living body. These are complex in the extreme, and differ greatly in the different diseases: the processes which take place in the tissues and in the blood as a reaction against the tubercle bacillus are quite different from those which are caused by the typhoid bacillus. The methods by which the various infections are combated differ very greatly, and this is a fact that we must never lose sight of in dealing with the problems of immunity and vaccine or serum treatment.

### HYPERSENSITIVENESS AND IMMUNITY.

We have now realised that the process of cure of an infective disease involves two apparently opposed factors: on the one hand, an increase in the defensive forces, so that the body tends to become immune; and, on the other, a specific raising of the sensitiveness of the body to the microbe or its toxin, so that it tends to become *less* immune. The latter process, though it is not always easily recognised, appears to be an essential precursor or accompaniment of the first. It is called anaphylaxis (i.e., the opposite of prophylaxis), and its clearest illustration is seen in one of the diseases I am discussing in these lectures—tuberculosis. The first effect of a tuberculous lesion is to raise the susceptibility of all parts of the body to the tuberculous toxin. Indeed, this substance—tuberculin—is practically without action on a normal person; it is only when he is sensitised by a previous dose or doses that it becomes a real toxin. It would appear that this is a process in the highest degree disadvantageous to the patient, and so it is: the tuberculous fever, when not due to secondary infections, is apparently entirely an anaphylactic reaction to doses of tuberculin too small to have any action on a healthy person. But it appears that this stage is essential to the production of immunity; out of this nettle—danger—we pluck the flower—safety.

Both anaphylaxis and immunity are *specific*. A person who is sensitised or who is immune to tuberculin retains his normal susceptibility to other poisons. It follows, therefore, that either of these phenomena may serve us in diagnosis. If a clear and unequivocal demonstration of anaphylaxis or of immunity to tuberculin or to the tubercle bacillus is forthcoming, it is definite proof of an infection, present or past. The problem which I have to discuss is how far the one or the other may be employed in practice in diagnosing an active tuberculous lesion.

I may remark in passing that the two stages—hypersensitiveness and immunity—may coexist. Thus, a person who has been treated with large doses of tuberculin may contain in his blood much anti-tuberculin, so that he may no longer react to large doses. Yet his tissues may be anaphylactic, and the disease may still spread. In some diseases the problem is an easy one, but this is not the case in tuberculosis, at least in adults. The difficulty arises in part from the nature of the tubercle bacillus, which renders it in many respects a difficult organism to work with, but it is more specially due to the fact that the great majority of adults have already some degree of acquired immunity to the disease. Hamburger has recently shown that in the poorer parts of Vienna no less than 94 per cent. of children become tuberculous before the age of 14 years; these results have been questioned, but they were confirmed by necropsy, and although the disease may not be quite so prevalent in most districts, it is undoubtedly very common for children to have a small tuberculous focus, causing no apparent symptoms, and not recognised unless death is brought about by other causes and a necropsy is performed. Yet this mild and latent tubercle may profoundly modify the susceptibility of the tissues of the patient. And perhaps even more important from this point of view is the fact that almost everybody is constantly being vaccinated against the tubercle bacillus *viâ* the alimentary canal and respiratory organs. Milk, as you all know, very frequently contains bacilli, and they are commonly present in the dust of the air we breathe; the traditional peck of dirt must contain innumerable millions of tubercle bacilli. If this is so, it follows that most of us must be undergoing a constant course of immunisation against the disease, and I might suggest that it is the lack of this form of preventive treatment which accounts for the great frequency of the disease in childhood. Be this as it may, the fact remains that adults as a class show definite signs of having been rendered partially immune to the tubercle bacillus, and this renders the diagnosis by means of the immunity reaction in them more difficult and unsatisfactory than in children. Thus the cuti-reaction, or von Pirquet's reaction, which is entirely satisfactory in childhood, is of comparatively little value in adults.

### CHANGES IN THE TISSUES.

The ultimate study of the processes which occur in any infective disease leads us to realise that, strictly speaking, no such thing as a local disease ever occurs. In all cases, however small the lesion, there are changes, often profound, in the blood and in all the tissues throughout the body. We believe, indeed, that the presence of a small and apparently quiescent tuberculous lesion may alter in an important way the method in which every portion of the body nourishes itself. These alterations in the tissues must almost necessarily affect the blood, and this again may react on the tissues, so that the whole process becomes one of extraordinary complexity. I allude to the alterations in the tissues first, since it is the tissues which elaborate the blood, so that changes in the blood (other than the presence of toxins, &c.) must necessarily be secondary to, and caused by, the changes in the tissues; and amongst the tissues in this connexion I must include the leucocytes, which appear to play a most important part in the elaboration of defensive substances. Furthermore, we must not forget that it is the tissues, the living and acting parts of our body, that have to be defended against attack. The blood, it is true, forms the first line of defence; the tissues are the country which the invader must conquer. The study of the way in which the tissues behave is therefore of the chief importance. Unfortunately it is much more difficult than the investigation of the blood, and our knowledge of it is much less advanced. Indeed, our knowledge of the altered behaviour of the tissues in infection and immunity was almost nothing until two or three years ago, and is due almost solely to recent researches on anaphylaxis, especially to tuberculin, as shown by the cuti- and ophthalmic reactions.

### ANTIBODIES.

Owing to the ease in which it can be investigated, our knowledge of these conditions in regard to their effect on the blood is much fuller; we may sum it up in one word—the presence of antibodies. By an antibody we mean a substance which we find in the blood serum as the result of the presence in the body of a foreign proteid, which we term its antigen. Thus if we inject a foreign protein, such as egg albumin, we find that the blood serum acquires a new property, that of precipitating a solution of egg albumin, such as was used for the injection. Here the albumin is the antigen, and we assume that the new property is due to a new substance, an antibody, which we call precipitin. It is a matter of some importance to recognise that antigens are, as far as we know at present, always proteids, or substances closely allied thereto; never fats, sugars, alkaloids, or other simple chemical compounds. It is noteworthy, too, that antibodies are always specific; diphtheria toxin acting as an antigen leads to the production of diphtheria antitoxin, which has no action on the toxin of tetanus. Speaking of ultimate molecules, this rule is apparently absolute, but in

ordinary experience a pure proteid is never seen, and the protoplasm and toxins of bacteria are highly complex mixtures. This is the explanation of some of the apparent non-specificity of some of the antibodies as we see them in disease.

If an antigen and its antibody are mixed they will always unite, and when this happens the properties, chemical, physical, or physiological, of the latter, are more or less profoundly altered. It is on this alteration of the antigen that our classification of the antibodies depends. Thus we recognise the following:—

*An Antibody Combined with an Antigen and the Result.*

| Antibody. | Antigen. | Action. |
|---|---|---|
| Antitoxin. | Toxin. | Neutralisation. |
| Precipitin. | Coagulable proteid. | Precipitation. |
| Agglutinin. | Cells, bacteria, &c. | Clumping. |
| Cytolysin (including bacteriolysin and hæmolysin). | ,, ,, | Prepares cells, bacteria, &c., for solution by complement. |
| Opsonin. | ,, ,, | Prepares cells, bacteria, &c., for ingestion by leucocytes. |

I include opsonin as an antibody, but with a certain amount of hesitation. It is not certain that it is an antibody, one of the reasons being that all persons contain in their serum a considerable amount of opsonin to the ordinary pathogenic bacteria, whereas they do not contain antibodies, or contain them only in minute traces. But there is no doubt that some, possibly all, of the true antibodies may play the part of an opsonin, so that I am justified in including them here.

## VARIOUS ANTIBODIES AND THEIR APPLICATIONS IN DIAGNOSIS.

The method of diagnosis of an infective disease by the demonstration of a specific antibody is theoretically simple. If the serum contains a large amount of an antibody to a pathogenic bacterium the presumption is that the person has, or has had recently, an infection with the organism in question. But in practice it is not always so simple. There are few examples of the application of the test which are so direct, so easy to carry out, and so certain in their results as the Widal reaction in typhoid fever, which, when properly performed, I regard as absolute. One of the causes of difficulty—for there are others—arises from the fact that it is not uncommon for normal and healthy persons to have in their blood small quantities of antibodies to various pathogenic bacteria. This is the case even with typhoid fever, for it is not uncommon for the serum of normal persons to clump the bacillus when but slightly diluted; hence—and this is a point on which I must lay much stress—all work of this sort must be strictly quantitative to be of value. We do not have to find the presence or absence of specific antibodies, but a significant amount, more than is present in health. This is especially the case in tubercle, in which disease, as I have already pointed out, opportunities for a process of accidental vaccination against the disease are frequently present. Keeping this in mind, let me give you a brief outline of the main antibodies to the tubercle bacillus and its toxin, and of their value in diagnosis.

1. *Antitoxin.*—I think we may regard it as proved that tuberculin—old tuberculin—is a solution of the real toxin of tuberculosis. But it is a toxin of a very remarkable kind, acting only on an anaphylactic person. The antitoxin to tuberculin—antituberculin—can be produced in animals by injecting large but carefully graduated doses of tuberculin. The serum of animals thus treated contains a new substance, the action of which is to neutralise the action of tuberculin on tuberculous subjects. Antituberculin can also be demonstrated in the blood of tuberculous patients who have been treated on the continental principle with large doses of tuberculin; serum from such patients mixed with tuberculin will prevent the latter from giving the von Pirquet's reaction on the skin of tuberculous patients. Non-treated patients may also contain antituberculin in small amount, and its demonstration affords a fairly good proof of a tuberculous infection. The proof of its presence is indirect, and I shall defer its consideration for the present.

2. *Precipitin.*—To demonstrate the presence of a precipitin to a bacterium it is necessary to obtain a solution of the bacterial protoplasm, and to mix it with the serum. If a precipitin is present the mixture becomes cloudy and a precipitate may form; thus, when an old, filtered culture of typhoid bacilli is added to serum from some typhoid patients (for the reaction does not always succeed) the phenomenon may occur, and when it does it constitutes a valid proof of a typhoid infection. Experiments on these lines with tubercle bacilli are difficult, since its protoplasm is very insoluble. T.R. approaches very nearly to such a solution; it consists of tubercle bacilli in a fine state of subdivision, closely akin to a true solution. It can be used for the test, and will occasionally be precipitated by tuberculous serum. Such tests are not very satisfactory, and yield no information that cannot be obtained by agglutination tests, which are much easier in execution.

3. *Agglutinin.*—This is the first antibody to the tubercle bacillus which was discovered and applied in diagnosis. The test is of some value, but stands on an entirely different footing from the Widal reaction. To begin with, it is not altogether easy to carry out. Special methods have to be employed for preparing the emulsion, since ordinary tubercle bacilli tend to clump spontaneously. Several methods are in use, but I have found it satisfactory to grind a large amount of tubercle bacilli (killed by heat, such as are used in the opsonic work) in normal saline solution saturated with chloroform, and then to centrifugalise at a moderate speed for an hour, or let it settle spontaneously for two days. The supernatant fluid forms a fairly stable emulsion, which may be standardised in the ordinary way. To carry out the test various admixtures are made of the serum and are incubated for four to six hours; the test is carried out in capillary pipettes and the results observed by the naked eye. Whatever method is used, the results are unsatisfactory in diagnosis but interesting theoretically. Thus Arloing and Courmont give the following table:—

| | Positive. Per cent. | Negative. Per cent. |
|---|---|---|
| Tuberculous patients ... ... ... ... | 87·9 ..... | 12·1 |
| Non-tuberculous ... ... ... ... ... | 34·6 ..... | 65·4 |
| Apparently healthy ... ... ... ... | 26·8 ..... | 73·2 |

Here we see very clearly that a normal person may, and frequently does, contain in his blood antibodies to the tubercle bacillus. Their mode of origin becomes clear when we consider Descos's results with the serum of infants.

| | Positive. Per cent. | Negative. Per cent. | Doubtful. Per cent. |
|---|---|---|---|
| Clinically tuberculous ... ... | 72·3 ..... | 12·3 ..... | 15·2 |
| ,, non-tuberculous ... | 12·7 ..... | 87·2 ..... | — |
| Doubtful cases ... ... ... ... | 50·0 ..... | 44·4 ..... | 5·5 |

Contrasting this with Arloing and Courmont's results we see that adult healthy and non-tuberculous cases have tuberculin agglutinins much more frequently than have infants. The practical value of a test of this sort is not great. Perhaps it might be increased if the estimation were carried out more carefully on quantitative lines. But it is quite certain that a case may progress from start to finish and never show the least trace of agglutinin in the blood. The test, therefore, cannot be an absolute one.

4. *Bacteriolysins.*—Of these we know practically nothing. Whether the tubercle bacillus is ever dissolved in the blood is as yet unknown, and the technical difficulties are so great that we can hardly expect valuable results from experiments *in vitro*. Possibly bacteriolysins do occur and play some part in the Bordet-Gengou reaction, with which I shall deal subsequently.

5. *Opsonins.*—The practical value of the opsonic index in diagnosis has been hotly discussed, and I do not propose to go over the ground at length to-day. I am the more justified in treating it in a brief and altogether inadequate way since Inman has recently published the results of a careful and painstaking investigation into its value, coming to conclusions with which, on the whole, I am in agreement. A low index (below 0·8) or a high one (above 1·2) is strongly suggestive of tubercle, and the greater the difference from these figures, whether by excess or deficiency, the more certain the diagnosis. This is generally admitted, but the value of the test is greatly reduced by the fact that, even in tuberculous cases, the index frequently falls within the normal limits. Inman, for example, found this to happen in

50 per cent. of cases of undoubted tubercle, and I think I should put the figure even higher. Thus, even if we were quite certain of our technique we could only diagnose 50 per cent. of cases of tubercle by the opsonic index—really fewer, since it is unsafe to make an absolute diagnosis from a slight variation above or below normal limits. To meet this difficulty methods have been devised of taking advantage of the fact that in an anaphylactic person a small dose of tuberculin causes a marked fluctuation of the opsonic index. The index is taken, and the patient is given a small dose of tuberculin or made to take exercise, or, if he has an accessible lesion, this is massaged; in any case, one or more subsequent determinations of the index are made and the results compared. As a rule, the first effect of the injection of tuberculin or of the procedures which are supposed to lead to an output of tuberculin from the lesions (auto-inoculation) is a lowering of the opsonic index—the negative phase—but occasionally this may be overlooked and the subsequent rise be the only indication of anaphylaxis. In a non-tuberculous person the index remains constant. This test is of great value, and it is the only one that professes to discriminate between an active lesion and the amount of antibodies, as shown by the "absorption-time," which started at 55 minutes, fell to 80 minutes, and then rose to 25 and ultimately to five minutes.

### ESTIMATION OF TOTAL ANTIBODIES.

So much for the methods by which we attempt to investigate the various antibodies separately. I now turn to methods by which we are enabled to gauge the amount of all the antibodies in the serum without attempting to discriminate between the various sorts. Two such methods are in use. The first does not call for extended notice. It is the *meiostagmin* reaction, introduced by Ascoli, and employed by Izar in the investigation of tuberculous sera. It depends upon the fact that when a serum containing an antibody is incubated for two hours in contact with its antigen a marked lowering of surface-tension occurs. This is measured by the number of drops which a measured quantity of the mixture forms when falling from a narrow orifice under constant conditions. The number of drops is measured before and after the incubation; if there is no antibody in the fluid the number is the same in the two cases, whereas if antibody and antigen are present there is a lowering of surface tension

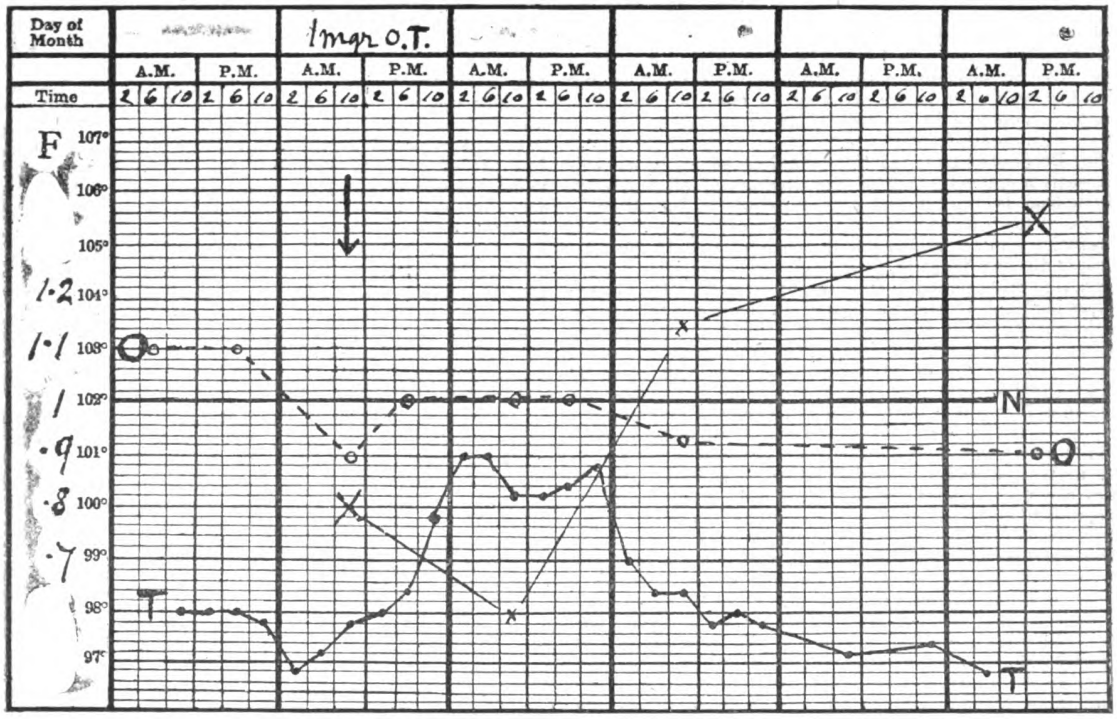

Chart showing: T, temperature; O, opsonic index; N, normal opsonic index; X, absorption time.

state of immunity or at least of altered susceptibility to tubercle that follows a complete cure. The criticisms I have to offer of this test are three: 1. The estimation of the opsonic index is tedious and difficult, and except when carried out with scrupulous care by a thoroughly trained experimenter fraught with liability to error. I am quite sure from what I have seen and heard that in many cases the results obtained are no better than guess-work. 2. In careful hands the error is believed to be about 10 per cent. If this were always in the same direction it would not matter, but if the error is sometimes in excess and sometimes in deficiency the total error may be serious. 3. The reaction does not always occur. I have met with at least two cases of undoubted tubercle in which no noticeable fluctuation of the opsonic index followed a dose of tuberculin, though the examinations were carried out with the greatest possible care. One of these cases is seen in the chart appended, which shows a very marked reaction after the injection of 1/1000 cubic centimetre of old tuberculin. It should be pointed out that the slight fall in the opsonic index occurred *before* the injection. The negative phase occurred, as is shown by the line between crosses, which indicates the total which manifests itself in an increase in the number of drops. The method is a general one, and has apparently given good results in the hands of its discoverer in the diagnosis of malignant tumours. I cannot speak of its value in the case of tuberculosis from personal experience; I have commenced to experiment with the method, but have not yet acquired sufficient command of the technique (which appears to be difficult) to obtain results of value. I believe that Dr. Hort has invented a simpler and more accurate method of estimating slight changes in surface-tension, and has applied it successfully to the diagnosis of tubercle, syphilis, and cancer.

### BORDET-GENGOU REACTION.

The other method, a much older one, is an application of the reaction of Bordet and Gengou, which requires a little explanation. I have already referred to the term complement but without defining it. Complement is a very fragile substance, allied in some ways to the enzymes, which is found in fresh serum, and which is supposed to play a part of great importance in protecting the body against disease. The antibody called bacteriolysin has in itself no action on

bacteria; but when these have been acted on by bacteriolysin (or, as it is usually termed, *sensitised*) they may be killed and even dissolved completely by the action of complement. Again, red blood corpuscles which have been sensitised by the antibody (hæmolytic amboceptor) which they produce when injected into a strange animal are also dissolved by complement. It is not yet quite certain whether the complement which dissolves bacteria is the same as that which dissolves red corpuscles, and it was in an attempt to settle this question that Bordet discovered the law which bears his name—a remarkable example of the practical advantages which may arise from what is apparently a useless research into a highly theoretical point. Bordet discovered that when antigen, antibody, and complement are present in a fluid, and a combination takes place between the two former, the complement present is abstracted. For example, if serum from an animal immunised to the typhoid bacillus or from a case of typhoid fever, and containing in either case typhoid antibodies, is mixed with an emulsion of typhoid bacilli or of an extract thereof (thus containing antigen), the two substances unite, and in doing so remove any variety of complement which may be present. This is readily demonstrated by adding red corpuscles which are saturated with hæmolytic amboceptor; if complement be absent, they will be unaltered; if it be present, they will become dissolved. The sensitised corpuscles simply act as an indicator to see whether a chemical action has taken place. We might compare them to a piece of litmus paper which has been used to see whether an unknown fluid has undergone a change in reaction after being mixed with an acid or with an alkali.

The Bordet-Gengou reaction supplies us with what is apparently a universal test for the presence of an antibody, and one that is independent of the nature of the antibody present. This is a point of considerable importance. Thus, the reaction can be used in the diagnosis of hydatid disease, a disease due to a parasite, though of large size, and accompanied, like other parasitic diseases, by an immunity reaction manifesting itself by the presence of antibodies in the serum. We do not know in the least what these antibodies are, whether they are to be regarded as antitoxins or other defensive substances, or what part they play in the struggle against the parasite. But they give the Bordet-Gengou reaction, a fact which enables them to be used in diagnosis. The method is simple: some of the serum from the patient is mixed with hydatid fluid, incubated at the body temperature, and sensitised corpuscles added. If hydatid antibodies are present no solution of the red corpuscles takes place, and then the diagnosis of hydatid disease can be made with almost absolute certainty. If there are no antibodies to the hydatid fluid the complement will not be absorbed, and this will be shown by the fact that the sensitised red corpuscles which are subsequently added will be dissolved and their hæmoglobin set free. This renders the diagnosis of hydatid disease unlikely, though it does not exclude it altogether, since it would appear that at times a hydatid cyst may remain latent and call forth no production of antibodies, those previously present being gradually eliminated from the blood. I have had but two examples of trying this test, in one of which it was positive and the other negative. I may say that in actual practice it is advisable to perform the test quantitatively, using various dilutions of the hydatid fluid, since normal blood may give some deviation with undiluted hydatid fluid.

### APPLICATION OF BORDET-GENGOU REACTION TO TUBERCULOSIS.

It is clear that this method should be of great use in the diagnosis of tubercle, or at least in the study of the immunity reaction in that disease, since, although we know but little of the nature of the antibodies that are produced, a very large number of researches have been carried out on these lines. The results have been extraordinarily various, some authors finding the reaction of some value, others finding it quite useless. Thus Simon and Hans got a positive reaction in 18 and a partial reaction in 2 cases out of 24, whilst out of 19 non-tuberculous controls they obtained a reaction only twice. Others have been less fortunate; thus Laub and Novotny got 4 complete, 5 partial, and 4 traces of a reaction out of 30 cases investigated. Butler and Mefford found it in only about half of their cases, and Cohn only in 15 out of 57. The same divergencies of opinion occur amongst veterinary surgeons who have used the test, Weber and Dieterlen finding it invariably absent in healthy and invariably present in affected cattle, whilst Bach could find no difference between the two. I think the discrepancies are to be accounted for in several ways, the most important of which is the fact that nearly all observers have used tuberculin as an antigen; this is true of Armand-Delille, Frugoni, Bach, Weber and Dieterlen, Besançon and Serbonnes, Noguchi, Leber, Butler and Mefford, Babes and Basila, and others. In my own experiments I began with old tuberculin and found it unsatisfactory, then experimented with the same fluid precipitated with alcohol and the precipitate redissolved in normal saline solution, which was not much better. The comparative uselessness of tuberculin for the test has also been noticed by Noguchi, who found that broth itself, and non-specific substances such as glycogen, would give the reaction. This may explain some of the positive results obtained with non-tuberculous sera, and it appears to be that the fact that tuberculous sera do not always react is to be accounted for by supposing that the bacilli in a tuberculous lesion are not always giving off enough tuberculin to cause sufficient antituberculin to be demonstrable by this test. And in any case we should not expect the process to demonstrate antibodies to the non-soluble portions of the bacilli. It was this and other reasons that led me to use an emulsion of tubercle bacilli. I have found since that Frugoni has done the same, and, like myself, has found the reaction of complement-absorption obtained by their use to be less sensitive than that obtained by the use of tuberculin as antigen, but more specific.

Another reason, which I found the force of more and more as I proceeded in my investigations, for the failure of the previous researches is the fact, already alluded to, that these antibodies may be present in health, and that, therefore, any method of investigating them must be accurately quantitative. I am quite convinced that no method, on investigation on these lines, will ever give us a ready-made test, applicable in all cases, for the presence or absence of a tuberculous infection. What it may be expected to give us is a measure of the amount of antituberculous substances in the serum, which, in association with the clinical facts, may have great value in diagnosis, and perhaps also in prognosis and treatment.

### QUANTITATIVE METHODS.

In quantitative estimations of the strength of a serum in antibodies, as estimated by the Bordet-Gengou reaction, there are several courses open to us. We may modify (1) the amount of the serum to be tested, keeping the other factors constant; or (2) we may dilute the antigen, so as to find the smallest amount which will give a positive reaction, the other factors remaining constant—this is the method which I have found most convenient in the Wassermann reaction; or (3) we may keep the amount of serum and antigen constant, and see how much complement the fluid can absorb. All these methods have been tried, and may be used; they are, however, rather complex for clinical purposes, which have been my aim throughout. I believe I have discovered a simpler method, and one more easily available for diagnosis. I found some time ago, and I believe that the observation was a new one, that in the case of the Wassermann reaction the absorption of complement takes place in a few minutes—five at most—at the incubator temperature. On trying similar experiments with sera in contact with emulsions of tubercle bacilli I found the time vary greatly, being on the average much shorter with tuberculous than with normal or non-tuberculous sera. This is what we might expect; the greater the amount of antibody the quicker we should suppose the reaction to be. I have therefore worked out what I term the *absorption-time* for a large number of sera, with results which I will show shortly.

I have always made use of the natural complement present in the serum, rather than attempt to keep this amount constant by heating the serum and then adding guinea-pig's serum, a method supposed, though I think not on very good grounds, to be more accurate. My chief reason for not doing so was that I was trying to work out a method of clinical value, and if I was able to do so by making use of the natural complement the results would be enormously more valuable from a practical point of view, because more easily obtained. I may say that I have made a considerable number of comparative experiments and do not find a serum

with a large amount of complement gives a long absorption-time, or *vice versa*. I cannot say whether such variations in the amount of complement as may occur in the same person's serum may affect the result, but have seen no reason to think so.

As regards the question whether I may not have been working with a non-specific process of absorption, I can only say that had this been the case I should have expected it to be proportionate to the amount of complement, which is not the case. Again, after an injection of tuberculin I have seen the absorption-time go down until it is longer than two hours; the absorption of complement, or its destruction at the incubator temperature, therefore, takes a period of time much longer than that given by ordinary serum. I feel fairly satisfied that the times which I measure are really to be regarded as an index of the amount of antibody present in the serum.

### TECHNIQUE USED TO DETERMINE ABSORPTION TIME.

As regards the technical details of my method, the first requisite is a standard emulsion of tubercle bacilli. This I have found it convenient to make up to such a strength that it contains 4 per cent. by volume of solid bacillary substance, this giving an absorption-time with normal serum of convenient length. I had hoped that this would prove an absolute standard, a desideratum of great importance, so that different workers can obtain comparable results. I find, however, that when I use bacilli from different sources I get somewhat different results, so that I now standardise each batch as it is prepared, getting a strength such that the average absorption-time for a healthy person is about 20 minutes. The emulsion is prepared with normal saline solution and is carefully sterilised by intermittent sterilisation before it is standardised, and is kept in sealed ampoules. It keeps for about a month or six weeks, after which it alters gradually. The serum from the patient is collected in an ordinary Wright's pipette, and not more is required than can be collected from an ear or finger puncture. The test has usually been applied the same day, but I have been able to trace no alteration after 24 hours, beyond which it is not wise to go.

The only other necessary ingredient is the emulsion of sensitised red corpuscles employed to see whether the serum contains fresh complement or not. I have adopted human corpuscles in view of the fact that they are always at hand. These have to be sensitised by the addition in definite proportions of the heated serum of a rabbit which has been injected with well-washed human corpuscles. I have found it most convenient to mix the red corpuscles and the serum and allow them to stand in contact for a few minutes rather than to add the corpuscles and serum separately; this simplifies the process somewhat. I find that a mixture of 1 part of washed corpuscles and 4 parts of immune serum gives good results. The strength of this immune serum is of some importance. It must be sufficiently strong, otherwise the corpuscles will not be thoroughly sensitised, and will then require more than the proper amount of complement for their solution, which error manifests itself as a short absorption-time. Neither must it be too strong, though this is less serious; if too strong the corpuscles will be so strongly agglutinated that they will sink before the complement has time to dissolve them. In this case correct results can be obtained if the mixture is stirred once or twice. The heated serum from the immunised rabbit has to be tested, and when the suitable dilution is found the serum is diluted to that degree and distributed into sterile ampoules in which it will keep for some months, though gradually becoming weaker.

It is necessary that the test should be carried out in a water-bath, and for this purpose the incubator made for me by Messrs. Hearson for use in the Wassermann test is very useful, though not absolutely necessary. Some sort of a water-bath, however, must be used, since it takes an appreciable length of time for a tube of fluid to reach the required temperature when placed in the warm air of an ordinary incubator, whereas if the tubes are kept surrounded by water at the desired temperature (38° C.) and the fluid placed therein, the small amount used will reach the temperature desired almost at once. The technique is as follows:—

A mixture of 1 part of the serum to be tested is mixed with 4 parts of the emulsion of tubercle bacilli in a tube in a water-bath at 38° C. and the time accurately noted. In 2½ minutes four volumes of the mixture are removed from the tube with a capillary pipette, into which also a single unit of sensitised blood corpuscles is sucked, and the two expelled into a narrow tube already standing in the water-bath. The process is repeated after 5, 10, 15, and 20 minutes, and for a longer period if necessary. The corpuscles in the tubes are allowed to settle (it is an advantage to give them a preliminary stir), and when this has happened the presence or absence of hæmolysis is read off, and the absorption-time is taken as that of the first tube in which there is no trace of hæmolysis. Thus, with my own serum, the tubes which have been incubated for 2½, 5, and 10 minutes give more or less marked hæmolysis, 15 minutes a trace, and 20 minutes *nil*, so that my absorption-time is 20 minutes. A control is necessary in all cases, and is prepared by making a mixture of serum and normal saline solution in the same proportions as the serum and emulsion of bacilli in the test, and sensitised corpuscles are added to make sure that the complement is present in sufficient amount. It is an advantage to allow this control tube to stand for half an hour to see that the complement is not destroyed in this length of time, though I have never found this to be the case. As a general rule there is but little weakening after one hour. Commonly with tuberculous sera, but very rarely with non-tuberculous, the absorption-time is less than 2½ minutes. It is not admissible to attempt to measure this direct, and where a more accurate measure of the time is required a combination of two methods must be used. The emulsion of bacilli must now be diluted in known proportions, and tested in exactly the same way. The results can be expressed by dividing the absorption time by the dilution. For example, a specimen of serum from a patient with tuberculosis of the breast gave an absorption time of 10 minutes with a 1 in 10 dilution of the emulsion; the time therefore was 10/10, or 1 minute. In a case of phthisis the time was 10 minutes with a dilution of 1 in 500, so that the absorption time was expressed as 1½ seconds. I need not say that all times under 2½ minutes are to be regarded as arbitrary, and I have not usually worked below this period. I am rather sorry that I have not done so, since it makes the results much more exact.

### RESULTS OF ABSORPTION-TIME TESTS.

Let me now quote my results. I have examined 34 cases of diseases other than tubercle and healthy persons. The average absorption time was 18·1 minutes, the maximum 35 minutes, and the minimum 2½; this shortened time was present in but three cases which were not thought to be tuberculous. In one of these cases I have some doubts; the person has suffered off and on from various ill-defined illnesses for several years, and although showing no definite sign of illness is not robust. Another serum came from a child with typhoid fever, and no details as to the presence or absence of tubercle were obtainable. The third came from a nurse who is said to have suffered from goitre, but who was otherwise healthy.

In tuberculous cases the most usual thing is to find the absorption time greatly reduced. In my cases the average time was 7·4 minutes, and times of less than 2½ minutes were found in 25 out of 56 sera examined, or 44·6 per cent. Thus, if we regard an absorption period of 2½ minutes as affording the criterion for the presence or absence of the test, we find it in 44·6 per cent. of tuberculous and 8·8 per cent. of non-tuberculous cases. If we take 5 minutes we find it in 66 and 11·7 per cent. respectively. The following table gives my results to the present time. In calculating the absorption time for the tuberculous sera I have taken all times under 2 minutes as if they were 2½ minutes exactly; this has the effect of lengthening the average very considerably:—

| Absorption time. | Tuberculous cases. | Non-tuberculous cases. |
|---|---|---|
| Less than 2½ minutes | 25 | 3 |
| 2½-5 minutes | 12 | 1 |
| 5-10 ,, | 9 | 2 |
| 10-15 ,, | 3 | 7 |
| 15-20 ,, | 2 | 11 |
| 20-25 ,, | 1 | 7 |
| 25-30 ,, | 2 | 3 |
| Over 30 ,, | 2* | 0 |

* One case 40 minutes; the other case 55 minutes.

Average of tuberculous cases ... ... ... 7·4 minutes.

Average of non-tuberculous cases ... ... 18·1 ,,

*Percentage of Cases.*

| Absorption time. | Tuberculous. | Non-tuberculous. |
|---|---|---|
| Under 2½ minutes ... ... ... ... | 44·6 ..... | 8·3 |
| Under 5 ,, ... ... ... ... | 66·0 ..... | 11·7 |
| Under 10 ,, ... ... ... ... | 82·1 ..... | 17·6 |

I quote the following results separately (they are, however, also inserted into the preceding table), as they were obtained by Dr. P. B. Ridge by my method, but quite independently, and may be taken to show that results similar to mine can be obtained by others.

| Non-tuberculous cases. | Absorption time. |
|---|---|
| 1. Normal case ... ... ... ... ... ... ... | 15 minutes. |
| 2. Typhoid fever ... ... ... ... ... ... | 15 ,, |
| 3. Anæmia ... ... ... ... ... ... ... ... | 30 ,, |
| 4. Gastric ulcer ... ... ... ... ... ... ... | 20 ,, |
| Average 20 minutes. | |

| Tuberculous cases. | Absorption time. |
|---|---|
| 1. Phthisis, doing well ... ... ... ... ... | 1 minute (calculated). |
| 2. ,, doing fairly well ... ... ... | 2½ minutes. |
| 3. ,, early, doing well ... ... ... | 2½ ,, |
| 4. ,, chronic ... ... ... ... ... | 10 ,, |
| 5. ,, no details ... ... ... ... ... | 10 ,, |
| 6. ,, doing well ... ... ... ... ... | 2½ ,, |
| 7. Tuberculous iridocyclitis ... ... ... | 15 ,, |
| Average 6·2 minutes. | |

The correspondence between the two sets of averages is very close. I think, therefore, that we may regard an absorption time shortened to 2½ minutes as affording strong presumptive evidence of tubercle—not absolute proof, for, as you will see, it may occur, though rarely, in persons in whom there is no definite evidence of the presence of tuberculosis.

APPLICATIONS OF TEST IN DIAGNOSIS AND PROGNOSIS.

Further, tuberculous cases do not always give a shortened absorption period. When I first realised this it occurred to me that a shortened time, which I take to indicate the presence of abundant antibodies (usually regarded as protective substances), might also indicate a powerful immunising response, and therefore a good prognosis. To a certain extent this is true: very short absorption times are usually met with in chronic cases which are doing well, and in quite general terms are, in definite tuberculosis, longer in cases which are progressing rapidly. The process, therefore, has some value in giving a clue to the prognosis. But it is very far from being absolute. This is shown in an extremely interesting way by the case that gave the longest absorption time in my whole series—55 minutes. This was from a mild case of primary tuberculosis of the larynx, which gave a very strong von Pirquet's reaction, and reacted to tuberculin internally. This patient was certainly not affected severely, yet his blood gave practically no signs of the presence of antibodies. He was treated with rather large doses of tuberculin (1/2000 c.c. O.T.), to which he reacted strongly, and after three such injections he showed no indications of becoming immunised to the substance. There was a well-marked negative phase after each injection, and in two of these I believe I was able to demonstrate the fact that this negative phase, characterised by a very long absorption time, was not due, or at least not entirely due, to a diminution in the amount of antibodies in the blood; it appears to be due in part at least to the presence of a substance which inhibits the linking up of antigen, amboceptor, and complement. This was shown by preparing mixtures of the patient's serum with serum containing a large amount of tuberculous antibodies; in all cases the absorption time of the latter was greatly prolonged as a result of the addition of the serum from the patient in whom there was a negative phase. These results were not due to the differences in the amount of complement present in the various mixtures, for in some cases mixtures containing a large amount of complement gave a short absorption time, and *vice versâ*. Not many of these experiments could be tried, as the phenomenon was only met with in one patient, and I should not have been altogether satisfied with the proof that the greatly prolonged absorption time in the negative phase (amounting on one occasion to more than two hours) was actually due to the presence of an inhibiting substance if I had not subsequently seen that Calmette and Massol have recently described a similar substance as occurring in the blood of animals during the course of immunisation against tuberculosis—i.e., under conditions similar to my own. According to them it interferes with the combination of antigen and antibody if added before the complement, and may occur in the same specimen of serum as the ordinary antibodies and mask their action. Taken together with Calmette and Massol's results my observations appear to show that such a substance may occur in human serum and its presence may explain the negative phase, a phenomenon for which no clear explanation has yet been given. It seems to me more likely that a small quantity of a new substance should make its appearance immediately after the injection of tuberculin or other antigen, rather than that there should be any appreciable diminution in the total amount of antibodies where these are abundant.

Thus it appears that a prolonged absorption time may be due (1) to the presence of antibodies in minute amounts only (this occurs in health or in tuberculosis, and as a rough general rule indicates a progressive disease); and (2) to the presence of this inhibiting substance (this does not necessarily indicate a bad prognosis). Judging from the few cases in which I have been able to put the matter to the test, a prolonged absorption time in a case of undoubted tubercle indicates a high degree of susceptibility to tuberculin, whether applied to the skin or injected; but a patient with a shortened time will also react.

I must add that I have been able to trace no apparent connexion between the amount of antibodies in the blood (as tested by the absorption time, the opsonic index, and the amount of complement).[1] This is shown in the following table:—

| | Absorption time. Minutes. | Opsonic index. | Complement value. |
|---|---|---|---|
| Control (normal) ... ... ... ... | 15 ..... | 1·0 ..... | 74 |
| Doubtful tubercle (Case A) ... | 30 ..... | 1·3 ..... | 76 |
| Mild tubercle of larynx ... ... | 55 ..... | 1·0 ..... | 94 |
| Phthisis ... ... ... ... ... ... | 2½ ..... | 1·2 ..... | 66 |
| Tuberculous glands in neck ... | 2½ ..... | 0·84 ..... | Not tested |
| Doubtful tubercle (Case B) ... | 10 ..... | 0·81 ..... | Not tested |
| Phthisis (another case) ... ... | 2½ ..... | 0·9 ..... | 134 |
| Lupus ... ... ... ... ... ... | 7½ ..... | Not tested ..... | 42 |

Other examples might be quoted.

In conclusion, may I urge the desirability of the acquisition of fuller knowledge than we now possess of the presence of antibodies in tubercle, and of their amount, as determined by any accurate quantitative method? I believe that if we were able to acquire a mass of information on this subject such as we have on the opsonic index we might gain very much useful information as to the pathology of tubercle, and perhaps much help as to treatment. On theoretical grounds it appears highly probable that an excess of antibodies in the blood, though probably not a cause of immunity to the disease, or at least not the only cause, should indicate a good prognosis, and is a thing to be striven for, whatever method of treatment we may adopt. In one or two cases under treatment I have seen a very marked improvement coincide with a great shortening of the absorption time. Thus, one patient with tuberculous glands in the neck had an absorption time of 30 minutes (tested on several occasions). After a course of tuberculin treatment his time was found to have shortened to two and a half minutes, and a marked diminution in the size of the glands had occurred. I have had but little opportunity for this class of investigation or for researches into the question of the occurrence of a negative phase after auto-inoculation, and should welcome cordially any further information on the subject, whether obtained by my own method or by any other.

[1] The method which I have evolved for the estimation of the relative amount of complement in different sera is as follows. Human red corpuscles are washed by three centrifugalisations from normal saline solution. They are then placed in a long narrow centrifugalising tube divided into hundredths and diluted with saline, and again centrifugalised until the volume of the deposit of corpuscles is constant. The supernatant fluid is pipetted off, and to each volume of corpuscles four volumes of a strong immune serum (rabbit) are added. These are incubated together for ten minutes or more and well mixed. Then four units of this sensitised emulsion are placed in a small tube (which must be clean and dry) and one volume of the serum to be tested is added, and the mixture incubated. Action is allowed to go on for a quarter of an hour, with occasional stirring, and the tube then centrifugalised very thoroughly. Then an amount which just fills five of the graduations in a Sahli's hæmoglobinometer are removed with a capillary pipette previously prepared for the purpose, placed in the comparison tube of the apparatus, and the amount of hæmoglobin estimated in the ordinary way. The figure thus obtained is regarded as the index of the amount of complement present. As a rule it lies between 25 and 150, the usual figure being 60–70. The method is quick and easy, and I believe it to be accurate.

ABSTRACT OF

# The Lettsomian Lectures

ON

# OPERATIONS FOR STONE IN THE MALE BLADDER.

*Delivered before the Medical Society of London on Feb. 6th and 20th and March 6th, 1911,*

BY WILLIAM F. HASLAM, M.B. BIRM., F.R.C.S. ENG.,

SURGEON TO THE BIRMINGHAM GENERAL HOSPITAL.

## LECTURE II.[1]

*Delivered on Feb. 20th.*

Mr. Haslam said that Joannes Jacobus Raw, who became the most famous lithotomist in his day, was born in 1668. For some years he travelled about Germany, Norway, Holland, and Spain. After a time he went to Leyden and commenced the study of medicine in the medical school. Then he visited Paris and studied anatomy and surgery under the best masters. At Amsterdam he taught anatomy and practised surgery. It was at this time that Frère Jaques appeared in the city and performed his new operation, which Raw saw and strongly condemned. Soon after this he was appointed lithotomist to the city of Leyden, where he made a great sensation. He died in 1719. When he first began to cut for stone he performed the Marian operation. When, however, Frère Jaques appeared in Holland, Raw was allowed to examine the bodies of those who died after being operated on by him, and from Jaques he learnt the operation he was then performing. After a time Jaques appeared again and performed his second and improved operation, and this operation Raw learned and adopted with great success. At the death of Jaques it was believed that Raw was the only surgeon in Europe who knew his true method. That was generally believed to be the cutting into the bladder behind the prostate, which was, however, his first and imperfect operation. Raw, from motives of his own, was mean enough to delude the profession into the idea that he continued to make that incision, while all the time he was incising the prostate according to the method adopted by Jaques in his improved operation. Nothing would induce him to impart to his greatest friends or pupils the way in which he made his deep incision. Cheselden worked out and successfully practised an operation which became associated with his name; and he freely imparted a knowledge of its principles and details to all anxious to learn. The report of his operation rapidly spread, and Morand, then the most celebrated surgeon in France, came over to England and saw the operation performed in St. Thomas's Hospital by Cheselden and learnt its details. Frère Jaques, in his first operation, aimed boldly at the body of the bladder with his dagger-shaped knife, leaving the prostate untouched and, though successful in extracting the stone, his patients died in large numbers. He demonstrated, however, that a wound of the bladder in this situation was not necessarily fatal. In his second and improved operation he gave up the use of his dagger-shaped knife and dissected carefully on to a grooved staff and made the deeper incision by cutting the prostate and neck of the bladder upon the groove of the staff. A feature of both these operations was that the incision was not limited to the perineum, but passed backwards into the ischio-rectal fossa, thus greatly facilitating the extraction of the stone. Then Raw followed in detail the two operations of Jaques, but refused to divulge the mode of performance of the second, and at his death, which occurred in 1719, the knowledge of this was lost. Cheselden, following the description of Raw's operation, failed, as he was only likely to do, to attain his success, and finally systematised the lateral operation. This he performed by a lateral incision between the accelerator urinæ and the erector penis, passing backwards into the ischio-rectal fossa and dividing the transversus perinei; the knife was then introduced into the membranous urethra, and, passing along the groove in the staff, divided the prostate. This was the operation he taught Morand, and, though then quite satisfied with it, he had the misfortune later on to wound the rectum in two cases and to experience a difficulty in extracting a large stone. In 1731, therefore, the year after Morand had returned to Paris with full details of the operation, he altered the mode of the deep incisions. Before long a period arrived when the straightforward operation of Cheselden, which required a knowledge of anatomy and a careful dissection, was replaced by one that was performed largely by the aid of mechanical contrivances, such as grooved lithotomes, concealed knives, and cutting directors.

We find that Le Cat, Frère Côme, Foubert, and Hawkins were pioneers in this direction, and that the simpler operations were suspended for a time to make way for others done with the assistance of these inventions. Surgeons had long been familiar with the gorget; it was, indeed, the lineal descendant of the conductor of Hildamus, and acted as a dilator and a conductor. An English surgeon, Sir Cæsar Hawkins, conceived the idea of converting its right edge into a cutting edge, so that it might be pushed along the groove in the staff and thus divide the prostate more easily and, it was thought, with less danger than by using the knife in Cheselden's operation; and for a time this instrument was generally used. The operation as originally formulated by Cheselden, that which he taught Morand, does not seem to have found entire favour with surgeons at that time, probably from the fact that though safe and easy when performed by one thoroughly acquainted with the anatomy of the parts and the details of the operation, it was by no means free from difficulties and dangers when undertaken by those less competent. The dangers were principally incident to the deep incision through the prostate and the introduction of the forceps. These dangers were likely to deter the timid and to try the nerve of any one who, without due consideration, had embarked on this operation. Consequently, gorgets almost without number were invented, each with some special feature which was supposed to render it a safe instrument with which to enter the bladder. If failure occurred after using one of these it could be attributed to the instrument and not to the operator. With the disappearance of the gorget a return was made to the simpler method as introduced by Cheselden, and the lateral operation in its original form held the field. As such it was known to those who commenced professional studies before about the year 1885, when as yet it had not felt the full effect of the revival, under improved conditions, of the suprapubic operation and of the great advance made in the crushing operation by Bigelow. From that time its decline was rapid. The first recorded case of the suprapubic, or high, operation is that by Pierre Franco of Lausanne in 1556. No more was heard of the method until 1581, when Dr. F. Rosset of Montpellier thought that a stone in the bladder might be removed by opening that organ above the pubes, using a grooved catheter as a guide on which to cut. In 1719 John Douglas, F.R.S., surgeon to the Westminster Hospital, performed the high operation in this country, and in 1723 published the details of four cases occurring in boys under 16, all of which were successful. Cheselden also, in the early part of his career, in 1723, published a treatise illustrating his method, which was similar to that employed by Douglas. A very considerable controversy arose as to whether Douglas or Cheselden, who both wrote on the subject in 1723, should be considered as having established the high operation as a mode of practice. Deschamps considered that the credit was due to Douglas. In 1820 Sir Everard Home of St. George's Hospital performed his modification of the high operation. He passed a catheter with an open end and containing a stilette along the urethra, and having exposed the bladder by a suprapubic incision, pushed the stilette through the bladder and enlarged the opening with a bistoury. In spite of these and other attempts to improve the operation it did not commend itself to surgeons as a routine method of treatment, and it was left for such cases as were considered unsuitable for the lateral operation. In 1880 Dr. Pietersen of Kiel, who was present at the reading of a paper by Garson on the high operation at the Congress of German Surgeons, published an account of experiments made to ascertain the relative position of the anterior fold of the peritoneum and of the upper border of the pubes. As the result of these papers the high operation was again taken up and gradually came into favour. It was now, with hardly any exception, the only cutting operation resorted to. The choice of method might lie between cutting and crushing, but if the former was decided on the suprapubic operation was performed as a matter of course.

[1] Abstract of Lecture I. was published in THE LANCET of Feb. 18th, 1911, p. 423.

# THE TREATMENT OF PNEUMONIA.[1]

BY DAVID B. LEES, M.D. CANTAB., F.R.C.P. LOND.,
CONSULTING PHYSICIAN TO ST. MARY'S HOSPITAL AND TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET.

WHEN your secretary, Dr. Vining, requested me to read before the Ealing branch of the British Medical Association a paper on the treatment of pneumonia I was glad of the opportunity once more to take up the consideration of this most important subject. It has interested me for many years. In 1885 I published a description of two cases of broncho-pneumonia treated with bleeding and ice,[2] and I devoted a large part of my Harveian Lectures delivered in 1903 to a study of the proper treatment of this common and fatal disease. So long as one patient out of every five or six attacked by pneumonia dies, and the total mortality reaches 40,000 deaths every year in the United Kingdom, the necessity for further consideration of the question of its treatment is only too obvious. What I wish to do now is to draw attention to some important matters connected with pneumonia and its treatment which seem to me not sufficiently regarded by the medical profession generally, and a due regard to which is in my opinion essential if a greater measure of success in treatment is to be attained.

I. The first point on which I would lay stress is *the importance of the earliest possible discovery of the local lesion.* Pneumonia consists, in the great majority of cases, in a local infection of the lung by pneumococci from the oral or nasal passages. It is of essential importance to determine precisely the situation of this primary focus in the lung and to attack it immediately by every means in our power; for, if left alone, the invading organisms increase at an overwhelming rate and may invade the whole lung. Every hour that passes diminishes the chances of successful treatment. In pneumonia, as in pulmonary tuberculosis, we shall not make much real advance in treatment until every medical practitioner has realised the duty incumbent on him of detecting the disease in its earliest localisation in the pulmonary tissue.

> Principiis obsta: sero medicina paratur
> Quum mala per longas convaluere moras.

For the accomplishment of this imperative duty it is necessary that we should all learn how much more important than auscultation is the constant practice of a careful and methodical percussion. We may learn much from the stethoscope, but in these early microbic infections of the lungs we may learn much more by the skilled use of our own fingers. For the earliest indication of a localised pulmonary invasion by the pneumococcus or by the tubercle bacillus is a local dullness to percussion, and the diminution at that same place of the functional activity of the lung. Dullness and diminished air-entry are the first evidences both in pneumonia and in pulmonary tuberculosis, but while the situation of these signs in tuberculosis is usually multiple and at certain definite situations in the upper parts of the lungs, in the pneumonia of adults a single area is generally first to be detected, and in the lower part of the lung; though apical pneumonia occurs occasionally and in children the infection is usually multiple.

We read in some descriptions of the disease that in some cases no physical signs are detectable until after the lapse of several days. I doubt whether this statement is ever true: I am sure that in most instances at all events it is founded simply upon a careless method of examination. Usually within 24 hours after the initial rigor of a pneumonia it is possible to demonstrate the existence of definite physical signs. They are at first merely dullness and lessened air-entry. But in pneumonia the picture rapidly changes, the dullness extends at an alarming rate, sharp inspiratory crepitation becomes audible, followed by bronchial breathing and bronchophony. At this stage the most careless physical examination may succeed in recognising a consolidation of lung.

The detection of the disease in its earliest stage is not merely a matter of scientific medical interest, it is of vital importance to the patient. Remember that while you are "fiddling, Rome is burning"! If your bedroom curtains caught fire, would you adopt an "expectant treatment" until the whole house was in a blaze? By an expectant treatment in pneumonia thousands of lives are lost every year.

II. *How is the initial lesion of pneumonia to be attacked?*—I answer unhesitatingly, *by the application of two icebags*, so placed as to include between them the inflamed area of lung. The pneumococcus is an organism which is very sensitive to changes in its environment, and in particular to changes of temperature. Dr. Eyre tells us[3] that "the range of temperature enjoyed by the pneumococcus is limited to about 14°, and is bounded by 28° C. on the one hand, below which no growth takes place, and by 42° C. on the other. The optimum temperature is undoubtedly 37·5° C." It is, therefore, not unlikely that persistent local reduction of temperature of a pneumonic lung, even though of moderate amount, may exercise a definite inhibitory influence on the rate of multiplication of the developing pneumococci. Fortunately, this is specially likely to be true in the worst cases of the disease, for Dr. Washbourn[4] showed from his experiments that *the greater the virulence the pneumococcus is found to possess, the more marked is its susceptibility to surrounding influences*, and the more difficult it is to cultivate. Less virulent "strains" of this organism were able to grow at lower temperatures. He found that a pneumococcus which was slightly virulent, and which would grow on artificial media at a temperature as low as 20° C., could by passages through animals be converted into a highly virulent type, which would not grow on artificial media at temperatures below 37° C.

It seemed to be very desirable, therefore, to ascertain by precise bacteriological investigation the comparative rate of growth of a given "strain" of pneumococcus at temperatures differing from each other as little as about 5° C. At my request Mr. S. Neave, M.R.C.P. Lond., at that time bacteriologist to the Hospital for Sick Children, kindly undertook this investigation in 1903, and in my Harveian lectures[5] I quoted his report. It was to this effect:—

> A colony isolated from [pneumonic] sputum was injected into mice, and the peritoneal and subcutaneous fluids resulting proved to be of exceptionally vigorous growth. In the first plating the peritoneal fluid was diluted by sterile saline solution, and an equal measured quantity was spread by a sterile glass rod on two agar plates. One was incubated at 39·4° C., the other at 32° C., resulting in 285 colonies at the higher temperature and 15 colonies at the lower. ..... In the second comparison one plate was incubated at 37·5° C., and produced 1568 colonies, while the second at 27·5° C. produced 690 colonies. In the third 38·5° C. produced 153 colonies, and 32° C. produced 42 colonies.

Mr. Neave's conclusion was:

> The above, although consisting only of one set of experiments, conclusively proves in respect of that particular strain of the organism that *a temperature of a few degrees less than that of the body prevents so active a growth.*

And he adds:

> It may be that the comparatively more vigorous growth at the lower temperature in the later experiments was due to the organism having been brought up on artificial media, and so had become less virulent. It may be noted that Dr. Washbourn points out that the non-virulent varieties have a stronger growth at lower temperatures than those of a virulent character.

These observations by Mr. Neave were made in 1903. Quite recently my friend Dr. Spilsbury, the well-known pathologist and bacteriologist of St. Mary's Hospital, has been good enough to examine the question a second time by careful investigations of his own. I quote his report in full.

"*Experiments on the cultivation of Fraenkel's pneumococcus at varying temperatures.*—The method employed was to take equal volumes of a pneumococcus emulsion in normal saline, and transfer to tubes of liquefied agar which were then poured into Petri dishes and solidified. In each experiment one set of these plate cultures was incubated at a given low temperature and a control series of plates was incubated at 37·4° C. (blood heat). At the end of a given time the number of colonies which had developed in each series of plates was counted. The plates which had been incubated at a low temperature were then kept at blood heat for a further period of two days, to ascertain whether the organisms which had failed to develop into colonies were dead or

[5] The Treatment of Some Acute Visceral Inflammations, and other papers. John Murray, 1904.

only lying dormant. The result shows a difference in this respect between Culture A, which was an old laboratory stock which had been grown on artificial media for a considerable time and which was therefore hardier and more likely to survive abnormal conditions, and Culture B, which was obtained from the lung at a necropsy in a case of lobar pneumonia, the emulsion used being prepared from the first set of cultures grown upon serum.

*Experiment 1.*—Culture A was incubated for three days at 32·5°–34° C. *84 colonies* were then counted. After a further two days' incubation at 37·4° C. *104 colonies* were counted. Control cultures incubated at 37·4° C. for three days developed *112 colonies*.

*Experiment 2.*—Culture A was incubated for three days at 29·5°–31·5° C. *45 colonies* were then counted. After a further incubation for two days at 37·4° C. *167 colonies* were counted. Control cultures incubated at 37·4° C. for three days developed *191 colonies*.

*Experiment 3.*—Culture B was incubated for three days at 29·5°–31·5° C. *19 colonies* were then counted. After a further incubation for two days at 37·4° C. *25 colonies* were counted. Control cultures incubated at 37·4° C. for three days developed *116 colonies*.

These experiments indicate that a lowering of the temperature of incubation of the pneumococcus of 3½ to 8° C. *not only retards the growth* of the organism, the retardation being greater the more the temperature is lowered, but *also destroys the vitality of some of the organisms so that they are rendered incapable of growing* when subsequently placed under more favourable temperature conditions. This effect is, as might be expected, more marked in the case of organisms recently obtained from body lesions and less inured to growth under artificial conditions."

Both Mr. Neave and Dr. Spilsbury point out that while the inhibitory effect of a lowered temperature is unmistakeable in all their experiments, it is most striking in the case of pneumococcal cultivations which have been grown as little as possible on artificial media. Mr. Neave's first observation, therefore, and Dr. Spilsbury's Culture B give the clearest indication of what is likely to happen when the temperature of a pneumonic lung is reduced by the application of icebags, and it is precisely in these two instances that the inhibitory effect is most marked, the diminution in Mr. Neave's case being from 285 to 15, or a reduction of 94·7 per cent., and in Dr. Spilsbury's from 116 to 19, or a reduction of 84 per cent.

Dr. Spilsbury adds the extremely valuable proof that the inhibition of growth was not merely temporary, but that it was an actual destruction of vitality of many of the organisms.

If we put these results together in tabular form we have as follows:—

| Neave. | | Spilsbury. | |
|---|---|---|---|
| 39·4° C. | 285 | (A) 37·4° C. | 112 |
| 32° C. | 15 (=5·3%) | 32·5° C.–34° C. After 2 days at 37·4°. | 84 104 |
| 37·5° C. | 1568 | (A) 37·4° C. | 191 |
| 27·5° C. | 690 | 29·5°–31·5° C. After 2 days at 37·4°. | 45 167 |
| 38·5° C. | 153 | (B) 37·4° C. | 116 |
| 32° C. | 42 | 29·5°–31·5° C. After 2 days at 37·4. | 19 (=16%) 25 |

Surely no further proof is needed. The bacteriological evidence of the inhibitory and even destructive effect of local cold on a pneumococcal focus is undeniable, and we are thereby prepared to accept the clinical evidence of the value of the icebag in the treatment of the early stage of a pneumonia. But before stating the results of careful clinical observation on this subject, it is desirable first to mention the precautions necessary for the successful employment of this method.

The employment of icebags in the treatment of pneumonia calls for two precautions. In the first place, the size of the right auricle must be carefully ascertained by light percussion in the fourth right intercostal space. One fingerbreadth of dullness is present in this situation in every normal heart; this is an elementary fact which has not yet found its way into the text-books, yet which can be verified by anyone. In an early stage of a pneumonia an increased extent of this dullness soon becomes perceptible. If it amounts to more than a fingerbreadth and a half, and if some dullness can be detected also in the third right space close to the sternum, it is generally wise to relieve the right heart by the employment of leeches (three or four for an adult, one or two for a child) before the icebags are applied. The neglect of this precaution may imperil the success of the treatment.

The second precaution necessary is to keep the legs and feet of the patient thoroughly warm by the employment of hot-water bottles and warm woollen stockings. A third precaution is useful, especially in the case of children; it is a frequent use of the clinical thermometer by a careful nurse.

If these precautions are adopted the treatment by icebags may be practised without fear. In the earliest stage it will sometimes abort the disease. When the pneumonia has advanced so far that this is no longer possible, it will yet limit the spread of the inflammation, diminish the local pulmonary engorgement, and repress the active increase of the pneumococci. Careful examination of a pneumonic pulmonary area before and after the use of icebags shows that the dullness is less absolute, and often also less extensive, and that the air entry is considerably greater.

Clinical evidence thus confirms the bacteriological results above stated, and is confirmed by them. The two together combine into a scientific proof of the value of ice in pneumonia, as when astronomical telescopic investigation of a region of the heavens determined by careful mathematical reasoning demonstrates the existence of a new planet. If this simile excites a smile, as a comparison of small things with great, it is sufficient to reply that it is a comparison of a fact on the recognition of which the life of a man (and often the happiness of many) may depend, with facts which, however interesting, are of no immediate practical importance.

Is it too much to hope that before the next generation of practitioners pass away all medical men will be so carefully educated in the practice of percussion that they will be able to demonstrate for themselves the beneficial effect of icebags on an incipient or early pneumonia? Medicine is both a science and an art; both must be cultivated with equal care and accuracy. For the art to ignore the science is stupid: for the science to neglect the art is suicidal. The art of medicine is often in advance of the science, as in the employment of quinine, arsenic, or mercury. Yet the practical success of the art must really be based on scientific facts, and it is our business to discover these facts as soon as we can. On the other hand, the medical science which has any real claim to the name cannot be confined to the laboratory; it must be constantly in touch with an ever-increasing accuracy of clinical observation. We hear much complaint nowadays of the bacteriological ignorance of the clinician, but how about the clinical ignorance of the bacteriologist?

III. The beneficial influence of ice applied over an incipient or early pneumonia being thus demonstrated by clinical observation and confirmed by bacteriological experiment, we may next inquire whether any additional treatment is of value in the attack on the invading pneumococci. The icebag is a weapon from without. Have we any medicaments which will penetrate into the innermost recesses of the lungs, and directly by an antimicrobic action or indirectly by an influence on the tissues attack the microbes from within? Traditional therapeutic scepticism does not see how this is possible. The possibility of benefit from volatile antiseptic drugs given by inhalation has been equally the subject of therapeutic scepticism in pulmonary tuberculosis. Yet the experience of the last five years has fully demonstrated to me the extraordinary value of such inhalation, provided that it is continuous and persistent, in early pulmonary tuberculosis. Under its use the temperature falls, cough is rapidly relieved, sputum diminished and more easily effected, the body-weight quickly increases, physical signs gradually and progressively improve, and tubercle bacilli become less numerous and finally disappear. For the evidence for these statements I must refer to the clinical details of 30 cases published in 1909,[6] and of 20 additional cases published in the following year.[7]

If, then, it is now certain that continuous inhalation of

[6] Brit. Med. Jour., Dec. 11th, 1909.
[7] THE LANCET, Nov. 19th, 1910.

volatile antiseptics does in some way repress the local development of the tubercle bacilli in the alveoli of the lung, may it not be possible that the same method may be useful also in the shorter and fiercer struggle with the pneumococcus? The time at our disposal is but short, yet even a slight assistance may possibly turn the scale. It might perhaps be thought that the severe dyspnœa of pneumonia would make it difficult or even impossible for a patient to wear a Yeo's inhaler. At the earliest stage of the disease, of which I am now speaking, this causes no difficulty, and at a later stage the acute dyspnœa which might prevent the use of an inhaler can generally be relieved by the employment of leeches.

As an example of its use in a very severe case, I may mention that of a man referred to in my valedictory lecture at St. Mary's three years ago, who was acutely ill on his admission, with clinical evidence of a generalised pneumococcal infection causing pneumonia, double pleurisy, and pericarditis. All the cases with this combination of physical signs caused by a pneumococcal infection that I had previously seen had been fatal. This patient was treated with five icebags, two over each lung and one over the heart, and he wore a Yeo's inhaler, which was refreshed every hour with six to eight drops of the same antiseptic solution which has proved so useful in tuberculosis. Being anxious to give him every possible chance I requested my distinguished colleague, Sir Almroth Wright, F.R.S., to examine his blood and to see whether a "vaccine" could be prepared. Sir Almroth Wright very kindly himself investigated the blood, but it was found to be sterile. Hence, no assistance from this side was available. The patient was admirably nursed, and under the free use of ice, the employment of hypodermic strychnine, and the constant inhalation of antiseptics he made a good recovery.

This was the first case of the kind in my experience in which this happy result was obtained, and I believe that the continuous antiseptic inhalation had certainly some share in bringing it about.

IV. A combined attack on the commencing pneumococcal infection having been thus organized by the use of ice externally and of antiseptic vapours inhaled into the lung, it remains to inquire whether we can simultaneously institute a third line of attack by means of a "vaccine therapy" which shall call into more active exercise the immunising reactions of the tissues, and by a modification of the blood serum succeed in rendering the invading organisms more susceptible to phagocytosis. It must be confessed that until recently there has not seemed to be much ground for hope from this procedure, although theoretically a localised infection like an initial pneumonia would seem to be a condition which ought to be benefited thereby. Perhaps the failures hitherto may be largely due to the late stage of the disease reached before the "vaccine" has been employed.

No form of treatment ought to be judged by its failure to cure a morbid condition already of great intensity. It is quite probable that a measure which can be of essential service in the early period of an infection may be powerless when the infection is far advanced. Hence it seems clear that if "vaccine therapy" is to establish its claim to usefulness in pneumonia it ought to be employed at the earliest possible moment after the discovery of the local lesion. But I think it is also clear that it ought not to be advocated to the neglect of the other measures of which I have spoken, the usefulness of which is already demonstrated. Therapeutic methods ought not to be jealous of each other. Let them combine their forces for the cure of the patient; and let the physician welcome help from every possible source.

The advantage of a combination of these different therapeutic efforts is clearly seen in the interesting cases, 24 in number, related in the admirable paper by Dr. W. H. Willcox and Dr. W. Parry Morgan read at the Belfast meeting of the British Medical Association in July, 1909.[8] These cases appear to afford very strong evidence of the value of a vaccine treatment in pneumonia, especially when an autogenous vaccine is employed. But the authors lay stress on the fact that they did not allow the use of inoculation to make them neglect other methods of treatment, and that "where necessary leeches, sponging, icebags, cardiac tonics, oxygen, &c." were also employed. It seems not improbable that their success with the "vaccine therapy" may have been due in part to the fact that they did not rely exclusively upon it, but used other means in addition, and more especially the powerful influence of ice. It is likely enough that a combination of therapeutic methods may succeed in accomplishing a result which could not have been attained by the employment of one method alone.

The evidence of the value of a vaccine therapy in pneumonia, published by Dr. Willcox and Dr. Parry Morgan, is sufficiently strong to make it very desirable that further observations should be made on an extended scale. The plan of investigation which seems to be required is the following. Let every case of pneumonia be very carefully examined when it comes under treatment, so that the exact localisation and extent of the pneumonic foci may be ascertained. Let it then be treated at once and thoroughly by the local application of ice and by the method of continuous antiseptic inhalation. Then let *every alternate* case be treated immediately by the injection of a stock pneumococcal vaccine, to be followed as soon as possible by a vaccine derived from the patient's own pneumococci, and also from his own streptococci or any other organisms which can be cultivated. If this plan were carried out in 400 or 500 cases, half of them being inoculated and half treated similarly but without inoculation, it would soon be clearly evident whether a vaccine-therapy is or is not of value in pneumonia. If it should turn out that its value is very great, this would not invalidate what I have said about ice and about antiseptic inhalation, any more than the unquestionable value of the antidiphtheritic serum has made it less true than before that the spraying of the throat every hour with a 1 in 1000 solution of perchloride of mercury is of extraordinary and life-saving value.

V. *The right heart.*—What I have said thus far has had reference to the earliest stage of a pneumonia. The next point to which I wish to draw attention demands careful and persistent observation throughout the whole course of the disease. It might indeed be described as the key of the clinical situation. And yet it is a point which is wholly ignored in most descriptions of pneumonia, is not even mentioned in some of the most recent monographs, and is constantly, and often with fatal effect, overlooked in practice. It is the question of the right heart.

The rapidly increasing obstruction to the pulmonary circulation causes a rise in tension in the pulmonary artery and a consequent tendency to a dilatation of the right heart. The first indications of this may often be detected by careful percussion in the fourth right intercostal space as early as the second day after the initial rigor. If the dilatation of the right auricle progresses so far that the dullness extends two fingerbreadths in the fourth right space dyspnœa becomes acute and is attended by restlessness, insomnia, cardiac oppression, and general distress. At this period the application of a few leeches will give immediate relief and allow of sleep. Very soon after they have completed their work the dullness of the right auricle will be found to have diminished by half a fingerbreadth (1 cm.) or more. The relief will usually last for 48 hours, unless the pneumonic process be extremely acute. At the end of 48 hours the auricle may again be over-distended and may require a repetition of the leeches. But this second relief generally carries the patient through to the crisis.

If the right auricle has been neglected until the fourth or fifth day of the disease it may be greatly over-stretched, especially if the inflammatory congestion of the lungs is widespread. In this case there is an urgent need for venesection. If no relief is thus given by blood-letting, the cardiac action becomes feebler and feebler, not because the wall of the left ventricle is poisoned by toxin, but because the contraction of the ventricular muscle is a peristaltic wave which reaches the ventricle *from the auricles*, taking origin at the sino-auricular node, a small mass of primitive cardiac tissue situated at the junction of the superior vena cava with the right auricle; and because the obstruction in the lungs and right heart prevents a due amount of blood from reaching the left ventricle. The feebleness of the pulse, therefore, in the later days of a pneumonia is not a reason against blood-letting, as a thoughtless observer might argue; it is a strong indication of its necessity. After blood-letting the pulse will be found to be decidedly stronger.

It was not without reason that our forefathers insisted on the necessity for bleeding in pneumonia. They misunderstood its mode of action, and their mistaken theory led to great

[8] Brit. Med. Jour., Oct. 9th, 1909.

excess in practice, but the relief of distress afforded by a moderate bleeding is unmistakeable. No drug in the Pharmacopœia, nor any combination of drugs, can produce the same relief. Yet the necessity for leeches or venesection is very generally overlooked by the practitioner, for the reason that he *has not acquired the habit of determining by careful percussion the size of the right heart in every case in which physical examination of the thoracic organs is required.* Till he has acquired this habit he will be almost certain to overlook the distended right auricle in pneumonia, and his pneumonic patients will suffer much discomfort that might have been prevented, and many patients will succumb before the crisis can occur.

The precise state of the right heart is the most urgent question in pneumonia. It ought in every case, but especially in the later days of the disease, to be the first question to be determined by a careful physical examination, taking precedence of any attempt to determine the locality or the extent of the pneumonic areas. From the fourth to the seventh days the condition of the right auricle very often calls for immediate relief before the lungs themselves are examined. Yet all this is generally entirely ignored. Is it any wonder that pneumonia is so often a fatal disease?

VI. *Cardiac stimulants.*—The most powerful cardiac stimulant in pneumonia is bleeding, for thereby the excessive tension in the right auricle which is paralysing its functional action is temporarily diminished, and it is quite remarkable how promptly the auricle recovers itself when once the opportunity is given. Certain drugs can give powerful assistance to a failing heart. Of these, strychnine in hypodermic injection is much used and highly valued. Oxygen by inhalation is also often recommended. It certainly relieves cyanosis, and thus by promoting the pulmonary circulation it gives help to the heart. But though oxygen often gives relief I have never seen it save a life. And neither oxygen nor strychnine, nor both combined, are of any great service in pneumonia unless the intra-auricular tension is lowered by judicious blood-letting.

Alcohol has long been advocated as a cardiac stimulant, and undoubtedly, by its vaso-paralytic action, it indirectly relieves the strain on a failing heart. But whether it is a direct cardiac stimulant, and, if so, in what way, is still a highly debateable pharmacological and therapeutical problem. Yet the remarkable paper read before the recent London meeting of the British Medical Association [9] by my colleague Dr. W. H. Willcox and Professor B. J. Collingwood, clearly shows that the inhalation of alcohol vapour combined with oxygen has a remarkably beneficial effect in cardiac failure. This was first discovered during experimental researches on chloroform poisoning in animals by Professor Collingwood. The discovery was utilised in clinical work by Dr. Willcox, who has made a large number of careful observations and precise calculations which are given in the published paper. The authors find that the administration of oxygen bubbled through absolute alcohol in an ordinary chemical wash-bottle is a marked cardiac stimulant in cases of heart failure, that it slows and strengthens a rapid feeble pulse, improves its force and volume, and causes a considerable rise in blood pressure. Its administration is pleasant and not irritating to the patient, and it gives rise to no ill-effects.

I had the pleasure of hearing Dr. Willcox read this paper at the Association meeting, and it so happened that a few hours later I was called to see a lady at the last extremity of cardiac failure. After relieving the right heart by leeches and the injection of strychnine, and arresting vomiting by giving nutrient enemata and stopping all food by the mouth, it was advised that the inhalation of oxygen bubbled through absolute alcohol should be tried. I was afterwards informed that this measure appeared to have a remarkably beneficial action on the pulse, and that the improvement after such an inhalation was decidedly greater than that obtained by an injection of strychnine.

It seems certain that we have thus secured a remedial measure of great potency; it is one which is quite simple in use, and it ought not to be forgotten. I suspect that its action is really on the cardiac and vascular centres in the medulla oblongata rather than on the heart itself. But, however this may be, its practical effect may be invaluable in certain critical conditions. And I would add that this fact emphasises the statement of the authors of this valuable paper that "sufficient attention does not appear to have been paid to the method of administration of remedies by inhalation into the lungs." I welcome this statement for the support which it gives indirectly to the method of treatment by continuous antiseptic inhalation to which I have already referred.

VII. *Diet.*—The addition of malted milk powder to milk greatly increases its nutritive effect, and at the same time diminishes the amount of fluid in the diet. This is of special importance when the right heart is dilated. Half an ounce of malted milk powder dissolved in 2 ounces of milk may be given every hour while the patient is awake: for a child the amount may be two teaspoonfuls in 1 ounce of milk. After the right heart has been relieved by leeches it is often useful to allow copious draughts of water to relieve thirst and aid the renal excretion. Half a pint of water may be given every three hours on the day following the use of leeches or venesection.

VIII. *Sleep.*—We are all apt to overlook the great importance of securing sleep *during the first two or three nights* of a pneumonia. An effective hypnotic should always be given at this time; if there is any pain hypodermic morphine is necessary; at this early stage it is quite safe. In the later days morphine must not be given unless the right heart has been relieved, and such relief will often enable the patient to sleep without any hypnotic. Every night's sleep is of importance in pneumonia.

These are, in my opinion, the essentials for a successful treatment of this common and fatal disease. If they were remembered and acted upon by every practitioner I believe that the mortality might be reduced very greatly, perhaps by as much as 50 or 60 per cent.

Weymouth-street, W.

# THE EDUCATION OF THE DEAF:

## ITS PRESENT STATE IN ENGLAND, WITH SUGGESTIONS AS TO ITS FUTURE MODIFICATIONS AND DEVELOPMENT.

BY MACLEOD YEARSLEY, F.R.C.S. ENG.,

SENIOR SURGEON TO THE ROYAL EAR HOSPITAL; MEDICAL INSPECTOR OF LONDON COUNTY COUNCIL DEAF SCHOOLS; LECTURER TO THE LONDON TRAINING COLLEGES FOR TEACHERS OF THE DEAF; EXAMINER TO THE JOINT EXAMINATION BOARD FOR TEACHERS OF THE DEAF, ETC.

### I.

DURING the three years that I have been working as medical inspector of the London County Council schools for the deaf I have had ample opportunity for judging of the working of the present system of deaf education in London, and the opinion to which I have been led thereby has convinced me that the whole system of deaf education in this country needs thorough reorganisation upon wider and more extended lines than is at present the case. A good deal has been achieved by the working of the Elementary Education (Defective and Epileptic Children) Acts of 1899 and 1903, but there is still much to be done before the country can turn out its deaf-mutes as reliable and self-supporting citizens, able to compete with their more fortunate hearing fellows in such a way that the percentage of those who become burdens upon the State is reduced to a minimum. The work of instructing the deaf is a very highly specialised branch of the teaching profession, requiring untiring patience and a high degree of adaptation. Indeed, if genius be an "infinite capacity for taking pains," then the teacher of the deaf has to be a genius of the first order. Only an intimate acquaintance with the work of this devoted body of men and women can give any idea of their labours, of the results which they achieve, or of the obstacles which they have to surmount. Moreover, the looker-on can detect the causes of their difficulties and the reasons why so many of their pupils fail to reach that standard of excellence to which theoretically they should attain under the modern system, and why a certain number of them have either to revert entirely to sign and manual methods of expression, or at least to supplement spoken language therewith.

To assert that the present system is a failure would be manifestly incorrect, but to say that it is a comparative failure is to enunciate a truism which can be established by facts patent to all who care to approach the matter with minds unbiassed by prejudice. That the teachers of the deaf are to blame for this comparative failure is most certainly not the case. The brilliant results which they can

achieve in an, at present, limited number of cases demonstrates clearly their capacity. There is no more self-sacrificing, hard-working, or devoted profession to be found, but its members are working under conditions in which it is impossible to reach perfection: they are contending against many obstacles, of which imperfect classification, inadequate legislation, and lack of sufficient financial assistance form only a small part. At the same time I would not wish it for one moment to be thought that the education of the deaf is not progressing. It is undoubtedly moving forward, but in the present state of our knowledge it is not moving with sufficient rapidity, and although deaf education is probably in a better state than it has ever been, it is in that stage of its evolution when those who are responsible for its well-being require to pause for a space and take a full and careful survey of its condition, with a view to its complete remodelling and reorganisation upon a firmer and wider basis, founded upon past experience and more accurate knowledge. The workers in deaf education comprise a body of young, active, and energetic men and women, who, starting with the experiences left them by their predecessors, are full of new ideas, have wider vision and greater capacity for improvement. They are beginning to see what Kerr Love in his "Study of the Deaf Child" has so ably pointed out, that deaf education must be based, not upon the consideration of different systems, but upon the study of the deaf child as an individual. Unless this fact be universally recognised, not merely by teachers of the deaf, but by the public at large and by legislators especially, the education of the deaf can only move slowly, with many halts and stumblings, towards greater perfection, and cannot reach that goal until several generations are past and gone and much public money wasted.

The whole question is one which must be looked upon from many different aspects—medical, hygienic, physiological, social, eugenic, and financial—and it is my intention in this series of papers to show how, by a due regard to these varied points of view, our present system of deaf education can be remodelled in such a way as to give far better results than have been attained hitherto—results that will fully justify any increased expenditure and will greatly increase the happiness, usefulness, and value to the State of a body of citizens whose only misfortune is, in the great majority, the impairment or loss of one of the most important, if not the most important, of their sense organs.

I have stated that the system of deaf education, as at present constituted, is a comparative failure. Such an assertion must be fully justified. With a view to ascertaining the progress of the scholars under present methods I recently introduced into the London County Council deaf schools a system of marking their attainments as regards articulation and lip-reading. This system is a modification of that suggested by Alexander and Mackenzie.[1] It classifies scholars in four groups—"Very good," "Good," "Sufficient," and "Insufficient"; and the test applied to 548 children in our deaf centres gave the results shown in the annexed table. Strictly speaking, these results apply only to 390 of the scholars (203 boys and 187 girls), as 158 (96 boys and 62 girls) were too young or had been too short a time at school to permit of their being judged with any justice to themselves or to their teachers. They have, however, been included in the table as "not marked."

[1] The Functional Examination of the Organ of Hearing in Deaf-mutes, Archives of Otology, vol. xxxvii., p. 507.

It will be noted that this table classifies these children primarily on a basis of mentality, and in order to be quite fair the 98 placed in the column, "Poor, subnormal, or mentally defective," may be left out of consideration altogether. The remaining 450 children of normal mentality are further grouped, according to the amount of speech which they possessed at the commencement of their education, into those who started with no speech at all (inclusive of a few in whom residual speech had been lost by neglect), those with residual speech, and those with natural speech. 140 of these scholars were too young or had been an insufficient time at school to allow of their being marked, leaving 310 whose progress under the present system of deaf education could be fairly accurately judged by this process of marking.

Taking, first, their powers of *lip-reading* it will be noted that of the 197 children who never had any speech 113, or 56·8 per cent., were "very good" or "good," whilst 84, or 42·6 per cent., were "sufficient" or "insufficient"; whilst of the 113 who were lucky enough to be left with residual or natural speech 84, or 73·5 per cent., were "very good" or "good," and only 29, or 25·6 per cent., were "sufficient" or "insufficient." This tends to show how much the retention of speech, which means largely the retention of motor memories of speech, helps in the acquirement of lip-reading—that is to say, in the appreciation of speech movement in others. It will be noted further that 30 of the non-speech children, or 25·1 per cent., were "insufficient"—that is to say, *absolute failures* at lip-reading—against 13, or 11·5 per cent., of those who had residual or natural speech.

Surely the present system of deaf education cannot be the best when it gives results such as these, in which 42·6 per cent. of the scholars in whom speech was originally absent are "insufficient" or only "sufficient" in their knowledge of lip-reading, "insufficient" meaning that they are incapable of reading other people's lips sufficiently to gather what they are saying, and "sufficient" that they are only a little better.

The teaching of lip-reading is, however, only one part of the aim of deaf education; it has also to give speech to the dumb—that is to say, it must so teach them articulation as to make their speech intelligible to those with whom they come in contact in after life. How many people—apart from teachers of or workers among the deaf—will not admit that they have difficulty in understanding the conversation of the average educated deaf-mute? How is this duty fulfilled in respect of the children who are under discussion in this analysis? Of 197 boys and girls who had no speech on admission, only 84, or 42·6 per cent., had articulation which could be marked, by the teachers themselves—who, from being continually in contact with the deaf, can probably understand them better than the average person—as "very good" or "good"; and only 17, or 20·2 per cent., of these (8·6 per cent. of the whole 197), belonged to the former category. Of those marked "sufficient" or "insufficient" (and the majority of the former would probably be understood with difficulty by anyone who was not used to the deaf), there were 113, or 57·3 per cent.; and of these, 60, or 53·09 per cent. (30·4 per cent. of the whole 197), were "insufficient"—that is to say, *oral failures*, children to whom the oral system had failed to give speech.

In strong contrast are the results with the 113 children who had residual or natural speech on admission. Of these, 107, or 94·6 per cent., were "very good" or "good" (the former, as is seen by the table, being in excess), whilst only 6, or 5·3 per cent., were "sufficient," and none were "insufficient." Here the system had succeeded in preserving to the great majority of its pupils the speech which they had retained when they had become deaf. I shall have to refer to this later when I come to the discussion of hereditary tendencies to speech in the congenitally deaf.

There is no need for my present purpose to analyse results under classification into congenital or acquired, totally or partially deaf. My object is rather to show that the present system does not produce a sufficiently high percentage of successes under existing conditions, and I consider that the figures just given amply bear out my contention that those who are now working have, under the present *régime*, too uphill a battle to fight, too many obstacles to contend with, too hard a task to master, to enable them to achieve the

successes that should come rightly from modern methods of deaf education.

That the failures are in greater proportion than should be the case is also demonstrated by the number of deaf persons who revert to signs as a method of communication, although I am inclined to the opinion that this reversion is partly due to the baleful effects of so-called missions to the deaf.

It is somewhat difficult to say definitely how long the oral system of deaf education has been in vogue in London, as it was practised to some extent by Joseph Watson at the British Asylum for the Deaf and Dumb (now the Old Kent-road Deaf School), founded in 1792. Watson was the nephew of Thomas Braidwood, who had taught privately in Edinburgh and in London prior to 1792, keeping his methods secret. Boswell[2] mentions that Dr. Johnson visited Braidwood's school and gave liberal praise thereto in his "Journal of a Tour to the Hebrides." "When he visited it," says Boswell, "a circumstance occurred which was truly characteristical of our great lexicographer. 'Pray,' said he, 'can they pronounce any *long* words?' Mr. Braidwood informed him that they could. Upon which Dr. Johnson wrote one of his *sesquipedalia verba*, which was pronounced by the scholars, and he was satisfied."

The birthplace of the oral system was, therefore, in the British Islands, but, strange to say, between 1809, when Watson wrote a book upon his methods, and 1865 it was so completely abandoned that in the latter year Van Asch wrote that "the articulation of the deaf and dumb is of rare occurrence in this country." It will be remembered that the deaf child who makes so pathetic a figure in Dickens's "Dr. Marigold's Prescriptions" was not taught upon the oral system. So completely had oralism disappeared in this country that when it was revived it was as the "German System," and as such it is largely known now—an interesting example of the regard paid to home products!

Kerr Love[3] has given the reasons for this remarkable decline from oralism to manualism as, first, that oralism was difficult for both child and teacher. I would here ask the reader to take note of the fact that Watson would not take pupils until the age of 9 years, a point of very great importance, as I shall show later; and, secondly, that the Abbé de l'Epée unselfishly conceived his sign and manual method and carried it out openly and above board, whereas the method practised by Braidwood in Edinburgh and London was exploited for his personal and family benefit and its details carefully kept secret.

There is no better exposition of the advantages of oralism than the proposition laid down by Watson as the basis of his teaching articulation. This proposition is quoted by Kerr Love,[4] and I quote it again here:—

> Words and phrases must excite ideas in us by association, and they excite ideas in us by no other means. ..... The more numerous the means of association the more perfect the recollection, or, in other terms, the more frequent the recurrence of words and their corresponding ideas to the mind. Thus persons who have all four means—that is, who can hear, speak, read, and write—retain a discourse much better, and have far greater facility in expressing themselves, than persons possessing only two of them, that is, illiterate persons who can hear and speak, but who cannot read nor write. Now, as deaf and dumb persons educated without articulation can only have two of the means—that is, the impressions made upon the eye by characters, the action of the hand in writing—can it be questioned that we render them an essential service by adding the actions of the organ of speech—a very powerful auxiliary, since by it words become, as it were, a part of ourselves, and more immediately affect us.

These words convey, better than any other, the superiority of oralism over other methods of deaf education.

The special teaching of the deaf child under the London School Board was begun in 1874, at Bethnal Green, with a class of about four or five children. Here a compromise was made between the two systems, teaching being partly oral, partly sign and manual.[5] In 1877, however, a pure oral school was started, and after the Milan Congress in 1880 oralism was more generally adopted, and it received great impetus after the schools became certificated by the Board of Education in 1893 and inspected by Mrs. Thurston Holland, who was a strong oralist. It was not until 1893 that an Act was passed making the education of the deaf compulsory, and not until 1907 that the ratepayer became taxed for the whole cost.

[4] Ibidem, p. 6.
[5] London at School, by H. R. Philpott. London: Fisher Unwin, 1904, p. 258.

The oral system has, therefore, been practised in our London schools for some years now, but it cannot be said to have had a fair chance until the past seven or eight years, as before then normal deaf children were mixed with mentally defectives and other scholars incapable of benefiting. These cases are now sent to the special institution for blind and mentally defective deaf-mutes at Homerton. I wish it to be understood that these remarks refer entirely to our State schools, and that I have not alluded to any results obtained in any other deaf schools in London. I shall, however, do so later.

The brief and concise sketch that has been given will serve to show that the education of the deaf of to-day is on a firmer basis than it has been hitherto. It is when a system has become established upon a sure foundation and has attained some degree of stability that the time has arrived at which it is advantageous to glance around, and, as it were, to take stock. By that means it can be seen what points are good and require developing, what points are weak and require strengthening, what points are uncompromisingly bad and require eliminating. I think that deaf education has reached that period now. The present system has been working for seven or eight years; it is high time to analyse results, to take stock, and to find out where is the profit and where the loss.

The results which I have already given above demonstrate the fact that if a number of scholars be taken consecutively and without selection, save as regards mentality, the successes do not compare as favourably with the failures as the theory of modern deaf education leads one to expect. Our first duty is to find out why this is so. Why, among children of normal mentality, who were either born deaf or who became deaf so early in life that they commenced their school instruction without the gift of speech, who are, in other words, both deaf and dumb, do we find that only 42·6 per cent. have learned to articulate well enough to merit classification as "very good" or "good," and that those who are absolute oral failures reach the high percentage of 30·4?

I believe that the answer to this question is two-fold—too late a commencement of education on the one hand, and a defective classification of the deaf child on the other. It is these two factors which will occupy mainly these articles, together with one or two matters of minor import so far as deaf education is essentially concerned, but of great importance as contributories to success. As regards the two main points, a careful examination of the physiological conditions under which the normal child acquires speech will demonstrate the former, whilst the application of the results of school medical inspection will modify and improve the latter.

Before entering upon the discussion of these two points, which will occupy the two succeeding articles, it will be as well to inquire into the results obtained elsewhere in the metropolis, and for this purpose I shall take the well-known school of the Association for the Oral Instruction of the Deaf and Dumb, at 11, Fitzroy-square. This institution, one of the most deserving charities in London, was founded in the year 1870 by the late Baroness Mayer de Rothschild, who, with the generosity so characteristic of the charity of her community, extended its benefits to embrace all deaf children, irrespective of denomination.

In the words of Mr. Sibley Haycock, the director, to whom I wish to express my indebtedness for the information here given: "The Fitzroy Square Oral School for Deaf Children is quite purely oral. The young pupils are trained to understand and to use spoken language from the beginning. Speech is introduced before the children can themselves articulate, and from the first day of their school life we begin to lay the foundations of the speech habit. They are talked to, directed, and instructed by speech alone. Later on, writing is used, but only to the same extent as in ordinary hearing schools. *Signs and finger spelling have no place in our system.* Not only do the teachers make no use of them, but they are rigidly excluded from the school-room. The little children in the kindergarten are allowed to express themselves by means of natural gestures and pantomime, but these forms of language are displaced as soon as possible by spoken and written words. Our aim is to make speech the medium of thought." (The italics are mine.)

I would draw attention to the fact that the method of instruction thus outlined appears to be based upon the lines of the normal physiological acquisition of speech by hearing

children, natural gesture and pantomime being allowed with the very young children in the kindergarten class, to be dropped with the acquisition of speech. A certain amount of gesture and pantomime is natural, but the greater the command over speech language the less are they used. The savage and the illiterate employ gesture more than the educated, and the savage more than the uneducated white. Indeed, the command of speech language can be tested by the putting of questions which can be answered by speech or by speech assisted by gesture, as, for instance, the request to define a spiral staircase. In the teaching of the deaf, therefore, where it is of paramount importance to teach as much speech as possible, any language by signs or gestures must be rigidly excluded as soon as elementary speech teaching is begun.

The average age of admission to 11, Fitzroy-square, since 1894, excluding pupils who had been under instruction before coming to the school, has been 5·8 years. The age at which the Act insists that education shall commence in the case of deaf children is 7 years, and, although a grant will be given by Government at the age of 5, it is seldom that pupils are admitted to the London County Council deaf centres before the age prescribed by law. I point this out because it is one of my contentions that the best results are not obtained by the oral system on account of the late commencement of deaf education.

The percentage of oral failures at Fitzroy-square, where the pupils are admitted at least one year earlier, taking the average, than in the London County Council schools, has been the subject of inquiry by me, and the reply of Mr. Sibley Haycock is as follows: "I can give no more definite answer to this question than to say that of the 18 children who have left school since my appointment here in 1907 we have had five oral failures—i.e., as regards speech and lip-reading—and these five were either subnormal as to mentality or entered the school quite late in life, and attended intermittently. One boy, for example, was 14 before receiving any instruction. This number roughly represents 27·7 per cent. of the pupils who have left since 1907."

In the analysis which I have given from our London County Council deaf centres, the subnormal in mentality have been separated and not taken into account, and we have seen that of the remainder of normal mentality the percentage of oral failures was 30·4. It is reasonable to consider that, were the oral failures at Fitzoy-square computed in the same way—viz., if those whose mentality was poor, subnormal, or defective were segregated—the percentage would be less than 27·7 and would therefore compare even more favourably with the results given above. One must, however, take into consideration, when making the comparison, that the teaching of this school has been consistently oral, and *purely oral* for 40 years—since 1870—whilst it was not until 1877 that an oral school was commenced under the auspices of the London School Board, and that, as I have said, the oral system has only had a fair chance under the Board's successor during the past seven or eight years.

I have already said that the education of the deaf is a matter involving wide issues, one which can be looked at from many points of view. I shall endeavour here to discuss it from some of these aspects, and I shall, therefore, postulate the present needs of this great and many-sided question as follows:—

1. The need of a classification of the deaf child which shall be upon a more scientific and more comprehensive basis than that at present in use. In dealing with this matter, I shall review the methods of education in other States and countries, and I shall make suggestions as to the best classification to be followed.

2. The need that the education of the congenitally deaf and of those very deaf children who, by reason of the early age at which they acquired their deafness, have not developed speech, should be commenced at a much earlier age than is now the general rule, in order that they may receive that physiological, in contradistinction to pedagogical, training to which they have as much right as the normal hearing child.

3. The need for the exercise of greater care of the deaf child whilst at school, by care committees and similar means, whereby it can be assured that his attendance at school is regular, his meals are adequate, that he is not neglected or exploited by bad or immoral parents, and that he is removed from the influence of bad companions and bad home surroundings.

4. The need for encouragement of the deaf child to mix with hearing people. To this end I would advocate a longer course of education and supervision by teachers, and, not unimportant, a more careful supervision of religious missions to the deaf.

5. The need to make an endeavour to diminish the number of deaf children requiring special education by the application of eugenic principles to deaf-mutism in the case of the congenitally deaf, and by a better care of the ears in children by medical practitioners.

1. *The need for a scientific classification.*—In order to understand fully the necessity for a better classification of the deaf child and its important bearing upon deaf education, it will be necessary to review briefly the methods at present obtaining in those countries in which such classification exists. By this means the best characteristics can be selected and the errors avoided.

Taking first *Germany*, it will be a surprise to many readers to learn that in deaf education the Germans are certainly lacking. Every deaf child is taught by the oral system, and by the oral system alone. "The German plan," says Kerr Love,[6] "of teaching the deaf by the universal application of the oral method is like the fitting of all kinds of sight defects with one type of eye-glass." Apparently in this country all types of deaf child are herded together to be taught on one system. In Berlin, it is true, many of the semi-deaf are sent to the board schools, where special arrangements are made for them, and there is in the same city a special school, instituted in 1907,[7] for "hard of hearing" children, with specially trained teachers, but it includes not only the hard of hearing children of the most varied capacity, but also deaf-mutes with residual hearing.

As a matter of fact, Germany, supposed to be so much to the fore in matters educational, but who is, by her methods, in danger of turning out uniform machines rather than rational men and women, has no proper deaf classification, and educates all her deaf by rote, without any regard to the deaf child individually.

For the sake of contrast, we will take *America* next, where is to be found a quite different state of affairs. There no special system is to be met with, but a deal of experiment. The period of instruction lasts longer (10 to 12 years in comparison with eight in Germany), and this tendency to keep the deaf child longer at school is further emphasised by a movement to start his education at an earlier age. Both these tendencies are, in my opinion, valuable, as will be seen later. Further, at the Gallaudet College in Washington the deaf youth of both sexes can take a university course and graduate like their hearing fellows. Altogether, as Kerr Love says, more money is spent on the deaf child in the United States than in any other country in the world, "and although not the shortest, nor the cheapest, nor in any sense the best way, this is one way of getting at the truth—and the Americans will get at the truth whatever it costs."[8] In this country at least a system of scientific and practical classification is being slowly worked out by experiment.

In two of the smaller states of Europe the education of the deaf is based upon a scientific classification, which, whatever may be its errors, takes into account the deaf child as an individual. These are *Schleswig-Holstein* and *Denmark*. The former, which has a population of about a million and a quarter, had some 132 children in its two deaf schools in 1906, the proportion of the semi-deaf being 30 per cent. They are classified on a basis of mentality. All go to a preparatory school, where after two years the dullest ("Class C") are set aside and allowed the help of free signing in addition to oral training, which, as in Germany, is the "system." The brighter ones, classed as "A" and "B," are removed to another school to be taught orally.

In *Denmark* the deaf-mute ratio is about 1 to 1600 of her population, and in 1906 the deaf children of school age numbered about 334. All are first sent, as in Schleswig-Holstein, to a preparatory school, which is situated at Fredericia. After one year these are classified according to their amount of hearing. Those who have residual hearing are drafted to a school at Nyborg, to be trained orally, no

[6] The Study of the Deaf Child, p. 4.

[7] Reinfelder: Schwerhörigkeit und Hörschule, Die Jugendfürsorge, 1909, Heft 3.

[8] The Study of the Deaf Child, p. 6.

distinction being made as to mentality. The totally deaf remain at Fredericia for another year, when they are again reviewed, this time from the mental standpoint, and the mentally dull are passed on to a school at Copenhagen, to be taught by the manual alphabet. The totally deaf of good mentality remain at Fredericia to be instructed by the oral method. This system has its faults, but it is rational and scientific, for it aims at a classification which takes due note of the individual capacities of the child, and is based upon the double foundation of mental capacity and residual hearing.

In *Russia* it is said[9] there are over 200,000 deaf-mutes, but only four educational establishments. For 30 years signs have been entirely abandoned in favour of oral teaching. Judging by the writer quoted, the deaf that are taught are taught well, especially by Mr. Enko, the present master of the Imperial Deaf and Dumb School. I am, however, unaware of any system of classification in this country.

In *Italy* there is no law to oblige the Government, on the one hand, to give, and the deaf, on the other hand, to receive, an elementary education, so that 73 per cent. remain in ignorance and isolation. Charity, however, provides for about two-fifths of the deaf who are of the age and condition to be admitted to a school. Although theoretically purely oral, practically the education offered is by a combined method. Further, although the necessity for classification of the scholars is admitted in theory, it is ignored in practice.

*France*—where the Abbé de l'Epée founded his world-famous school in 1760, and which was thus the pioneer country in deaf education a century and a half ago—is by no means in the foremost rank in that great work now. It numbers 65 schools for the deaf, some belonging to the State, others private, others managed by the clergy (priests or brothers), and others again managed by religious communities. These schools contained, in 1907, 3894 children. According to M. Adolphe Bélanger,[10] however, no classification of the pupils is attempted.

In *Holland* there are four schools—at Groningen, St. Michiels-Gestel, Rotterdam, and Dordrecht. These all originated in private charity and enterprise, there being no Government compulsory education for the deaf. Instruction is mainly oral, and there is some attempt at classification in the two large institutions at Groningen and Rotterdam, where the classes are more or less divided on a mental basis. There is a "class for abnormals" at the former school, and at Rotterdam a "class for very dull children." At Groningen there is also a special class for semi-deaf children.

Passing now to our own country, it will be found that the three kingdoms are not particularly united in their methods. In *Scotland* the system of instruction is that known as the combined method.[11] Scotland is, however, lucky in possessing an enthusiast in deaf-mute work in Kerr Love, whose knowledge of the deaf-mute and his education is unrivalled. Largely owing to his exertions a system of classification is being evolved. Knowing Kerr Love as so persistent an advocate for the study of the deaf child and the subordination of all systems and methods to him, it can be said with confidence that, if the authorities in Scotland will but be guided by the experience and scientific reasoning of this authority, that country will take first rank among the deaf-educating nations.

*Ireland* has no legislation as to deaf education, and there is no compulsion for the deaf-mute. Instruction is carried out at Belfast, Cabra (Dublin), and Claremont. The teaching is mainly manual, there being a small oral school at Claremont, near Dublin. Classification is apparently practically non-existent.

In *England* classification is in a condition of evolution; it is, therefore, all the more important that those who are in authority should have the matter laid before them in all its aspects. This is especially the case in London, where deaf education is, I hope, on the eve of important changes. The present arrangement in the metropolis—that under the London County Council at least—is that there are seven day-schools and three semi-residential schools with a roll of between 600 and 700 scholars. These schools are scattered about London, so as to serve different districts as far as possible. Instruction is oral, except at Homerton, a semi-residential school to which the mentally defective and blind deaf-mutes are sent, with a certain number of oral failures. The method in use there is adapted to the individual child. The sexes at Homerton and at the seven day-schools are mixed, but at two of the semi-residential schools, at Wandsworth and Anerley, they are separated, girls going to the former and boys to the latter. These are in the nature of advanced schools, children between the ages of 13 and 16 attending them and being instructed in dressmaking, laundry work, bootmaking, tailoring, carpentry, and baking. Laundry work, bootmaking, and carpentry are also taught at Homerton.

It will be seen that in London some endeavour at classification is made upon a basis of mentality, and as I have already pointed out it was not until some provision for mentally defective deaf-mutes was made by the opening of the Homerton school that the oral system really had a fair chance given to it. There is, further, an additional classification based upon residual hearing now beginning. My great object is to see the scheme of deaf education embracing not only the very deaf and the semi-deaf but the deaf of all and every degree. As long ago as 1906 I drew attention to the neglect of the slightly deaf child in England[12]; and the following year I read a paper upon the same subject before the Second International Congress of School Hygiene held in London.[13] Since that time the progress of school medical inspection has been such that we are able to detect some at least of the deaf children in the elementary schools, and these are specially seen by me with a view to educational treatment. Of the slightly deaf among them a number during the past year (1910) has by this means been put in the way of treatment, whereby their deafness has been arrested and they have been able to return to their original school. Others have been judged able to return to their original schools provided they are put in the front row.

The greatest step forward that has been made in our London system during 1910, however, has been the institution of special classes for "hard of hearing" children, by which term is meant those scholars who are too deaf to be educated in the elementary school, even if placed in the front rows, but are not deaf enough to be put among deaf-mutes and very deaf children. The success of the first of these classes is undoubted, and it is sincerely to be trusted that others will shortly be opened. The lines upon which they should be run will be discussed later, but I am pleased to say the idea is that advocated by me in 1908.[14]

It will thus be seen that the evolution of a system of classification is in London in an active stage.

Having thus detailed the state of deaf education in different countries in the civilised world it remains to be seen what improvements can be made. The first question for discussion is, therefore, What would be the most practical scheme for the classification of the deaf child for purposes of education, and the one most likely to give the best results?

*(To be continued.)*

[14] Deafness in Relation to School Medical Inspection, British Journal of Children's Diseases, November, 1908.

DEVON AND CORNWALL EAR AND THROAT HOSPITAL, PLYMOUTH.—The annual meeting of the subscribers to the Devon and Cornwall Throat Hospital was held on Feb. 10th. The medical report was satisfactory, and showed an increase in the number of operations. This, the committee states, "was largely due to the inspection of school children, and raised the question as to their treatment. The State now insisted on the treatment of these children for various defects, and as in other cases where the State insisted on treatment the State should pay for it. It was hardly fair to the institution or to the honorary medical staff that the whole burden should be thrown on them." The financial statement showed a small favourable balance. The meeting decided to enlarge and improve the hospital at an estimated cost of about £2000, and a special appeal will be made for that object.

# NOTE UPON THE EXAMINATION, WITH NEGATIVE RESULTS, OF THE CENTRAL NERVOUS SYSTEM IN A CASE OF CURED HUMAN TRYPANOSOMIASIS.[1]

BY FREDERICK W. MOTT, M.D. LOND., F.R.C.P. LOND., F.R.S.,
PHYSICIAN TO CHARING CROSS HOSPITAL; PATHOLOGIST TO THE LONDON COUNTY ASYLUMS.

THIS is the first c ase in which "a chance has occurred of examining a cured case of human trypanosomiasis post mortem," according to the statement of Mr. C. A. Wiggins, the acting principal medical officer of the Uganda Protectorate, who has kindly forwarded me the tissues for microscopic examination.

*Summary of the history of the case.*—A Sikh, belonging to the 4th K.A.R. (aged 30 years at death), was found to be suffering from trypanosomiasis in June, 1905, and received treatment with inorganic arsenic. The previous history, as far as ascertainable, compiled from extracts of reports and history sheets, is given in the account below, but, in brief, it may be assumed that the drug was given intermittently for 18 months or more and pushed till toxic symptoms of neuritis, mental dulness, &c., rendered further energetic treatment impossible; trypanosomes were then no longer obtained by puncture of the glands. Unfortunately there is no note of lumbar puncture having been performed until a few months before death, therefore we do not know whether invasion of the sub-arachnoid space ever occurred either before or after the treatment. But it is probable that trypanosomes were never present in the cerebro-spinal fluid, for if they were the symptoms of sleeping sickness would in all probability have come on in spite of treatment by atoxyl. Sir David Bruce in December, 1908 (that is, three and a half years after the trypanosomiasis had been discovered), saw this man and stated that he appeared to be in excellent health. A year later he was seen by Captain A. E. Hamerton, R.A.M.C., and Captain H. R. Bateman, R.A.M.C., who reported no symptoms of sleeping sickness. They made a very careful investigation of the blood, both by microscopic examination and by experimental injection into monkeys; the results were negative. In June, 1910, lumbar puncture was performed, and 17 cubic centimetres of fluid were withdrawn; the centrifuged fluid showed no lymphocytosis or trypanosomes; and injection of the fluid into a monkey was followed by negative results. The patient was attacked with pneumonia in August, 1910, and he died three days after admission to the hospital. At the post-mortem examination grey hepatisation of the whole right lung was discovered. Beyond fibrosis and induration of the cervical and inguinal glands there was nothing noteworthy in the appearance of the organs and tissues. The brain was quite normal in appearance, and there was no excess of fluid. It may be mentioned that this man had contracted syphilis on July 27th, 1906, and he was treated for some time with mercury, and a note on Feb. 15th, 1908, is as follows: "Condition the same as August 6th, 1907, but no trypanosomes found in blood or glands, due to fact of taking mercury for syphilis."

*Histological examination.*—Sections were prepared of portions of the cerebrum, cerebellum, and medulla oblongata, by all the methods which I have previously adopted for the examination of the tissues in cases of sleeping sickness. I found no trace of the characteristic meningeal and perivascular infiltration, nor of gliosis. Sections of the spleen, liver, and kidney were also examined with negative results. I have shown that there is a parallelism between the intensity of the signs and symptoms of sleeping sickness and the diffuseness and intensity of the lymphatic perivascular infiltration with lymphocytes and plasma cells which is the main cause of the clinical phenomena. It may be asserted that this case proves that human trypanosomiasis is curable, but it does not prove that sleeping sickness is curable, for I contend that the diagnosis of sleeping sickness can only be made when there is proof that the trypanosomes have invaded the sub-arachnoid space. The case emphasises the importance of early diagnosis of the infection and the value of early energetic treatment by organic arsenic preparations. How far the administration of mercury assisted to complete the cure is uncertain.

The previous history of the case as far as ascertainable (compiled from extracts of the reports and history sheets of Dr. H. B. Owen, medical officer to the Civil Hospital, Entebbe), may be summarised as follows:—

June 22nd, 1905: Trypanosomiasis. Received treatment inorganic arsenic. Dec. 4th, 1906: Gland puncture. Trypanosomes +. 6th, 7th, 16th, and 17th: Injections 2 c.c. atoxyl 20 per cent. 18th: Glands trypanosomes +. 28th: Glands trypanosomes −. Atoxyl 20 per cent., 2 c.c. 29th: Repeated atoxyl 20 per cent., 2 c.c. Jan. 1st, 1907: Glands trypanosomes −. Feb. 8th: Glands trypanosomes −.

*Condition.*—Arsenical neuritis. Drowsy-looking. Rheumatic pains. August 6th, 1907: Condition far from satisfactory. Irregular fever, rapid pulse. Dull and stupid. Cervical glands enlarged. Trypanosomes not found in glands since March. Energetic treatment with arsenic impossible owing to symptoms of poisoning rapidly appearing. Feb. 15th, 1908: Condition the same as on last date, but no trypanosomes found in blood or glands, due to the fact of taking mercury for syphilis (contracted July 27th, 1906).

*General condition.*—Dec. 16th, 1908: Strong, well nourished. No tremors. Reflexes normal. Gland puncture and blood examination trypanosomes −. Differential count. Lymphocytes 70 per cent. Some tendency to drowsiness when unoccupied. Last treatment, two injections kharsin, May, 1908. 18th: Proceeded to Mpumu to do duty with the Royal Society's Sleeping Sickness Commission. Report by Sir David Bruce—"This man appears to be in excellent health." Returned to Entebbe. Dec. 16th, 1909: Report by Captain Hamerton and Captain Bateman, Sleeping Sickness Commission, Mpumu—"No symptoms of sleeping sickness."

*Blood examination.*—Peripheral blood: Negative results, 14 occasions. Centrifuged peripheral blood: Results negative. Blood from median basilic vein: Results negative. Blood from median basilic vein centrifuged: Results negative. Dec. 16th, 1909: 4 c.c. blood from median basilic injected into monkey. 29th: 5 c.c. blood from median basilic vein injected into monkey. First monkey examined 15 times; results negative. Second monkey examined 12 times, with negative results. June 13th, 1910: Lumbar puncture 17 c.c. Cerebro-spinal fluid abstracted centrifuged. Trypanosomes −. No excess white cells. 12 c.c. injected into monkey. Monkey examined twice weekly over one month; results negative.

*General habits.*—Intemperate. Had had gonorrhœa and syphilis.

*Post-mortem appearances 14 hours after death.*—Body of lean but in no way emaciated man. Externally the cervical and inguinal glands were small, hard, and shotty. Chest: Parietal and visceral pleura adherent right side, due to recent pleurisy. The right lung weighed 58 oz. On section the whole lung was in a state of grey hepatisation. The left lung weighed 14 oz. Pleura and lung substance normal. Heart: Weight 12 oz. Right heart distended with blood clot. All chambers and valves normal. The glands at the root of lungs and around bronchi and trachea were enlarged and soft, and some were purulent. Microscopical examination of this pus showed organisms resembling pneumococci. The liver weighed 89 oz. and was enlarged and congested. On section it was soft and friable. Probably some fatty change. No obvious fibrotic changes. The spleen weighed 14 oz. It felt hard to the knife on section, was pale in appearance, and there was an excess of fibrous tissue on cutting open. Kidneys: Right, weight 5 oz.; left, 6 oz. Both were swollen, the kidney substance bulging from the capsule when cut into. Both capsules were a little adherent. Cortices undiminished. The whole kidney substance appeared a little paler than normal. The pancreas and suprarenals were normal. The stomach was slightly dilated; no gastritis; some post-mortem staining. The intestines were normal; mesenteric and retro-peritoneal glands not enlarged. Brain: Calvaria normal. Weight of brain, 52 oz. No thickening of membranes. Brain substance normal. Ventricles normal in size and no excess of fluid. Portions of the liver, the spleen, the kidneys, and the cerebral cortex and cerebellum were preserved for microscopical examination in England.

Nottingham-place, W.

# REMARKS ON THE TREATMENT OF SYPHILIS WITH DIOXY-DIAMIDO-ARSENOBENZOL ("606").

BY C. F. MARSHALL, M.SC., M.D. VICT., F.R.C.S. ENG.

IT is much to be regretted that arsenobenzol has been introduced in a manner which is more in accordance with the methods of commercial enterprise than with the ethics of scientific medicine, for such methods are naturally calculated to create a strong prejudice against it. Nevertheless, as its inventor is one who holds a high position as a medical scientist, it is necessary to deal with this preparation on its merits and to judge, if possible, the position which it is likely to occupy in the therapeutics of syphilis.

The two main questions to be decided are: first, is arsenobenzol capable of replacing mercury and iodides in the treatment of syphilis? Secondly, if it is incapable of doing this, is it of value as a third weapon against syphilis? Before any drug can replace mercury and iodides it must be proved capable of producing one or more of the following effects: (1) the realisation of an abortive cure of syphilis; (2) the prevention of tertiary or parasyphilitic manifestations; and (3) the healing of syphilitic lesions with greater rapidity, greater constancy, and at the same time with less liability to relapse and recurrence than is the case with mercury and iodides. It must also compare favourably with the latter as regards dangerous toxic effects. Let us see whether arsenobenzol has been proved to fulfil any of these conditions.

1. On the strength of its remarkable effect on relapsing fever in rats it was at first hoped that arsenobenzol might effect an abortive cure of syphilis, or *therapia sterilisans magna*. However, this idea has, I believe, been abandoned by most of the recent investigators. In any case, an abortive cure of syphilis is impossible to prove, at any rate in the human subject, owing to the long latent periods that may elapse between the early and late manifestations. Those who pin their faith on the Wassermann reaction claim that a persistently negative reaction signifies a cure; but, considering our ignorance of the real nature of this reaction, and the knowledge that it is not specific for syphilis, it is doubtful if this evidence can be accepted as absolutely conclusive. Moreover, as Flashman and Butler[1] have pointed out, in a case of syphilis which is apparently cured an encapsuled focus of disease may remain in some part of the body, incapable of producing the bodies which cause the complement deviation of the Wassermann reaction, unless roused to activity by some extraneous cause. Obviously, such a case might continue to give a negative reaction, which would be misleading.

Another fact often brought forward as evidence of the cure of syphilis is the occurrence of reinfection; but in the light of recent observations it appears that reinoculation with syphilis may be successful before the original infection is extinct. A few years ago Finger and Landsteiner[2] suggested that as a syphilitic subject might have recurrent lesions for years due to his own endogenous spirochætæ, so might he have lesions during the same time due to exogenous spirochætæ. More recently Pinard[3] has shown that reinfection, or rather superinfection, can take place during the primary period up to 31 days after the appearance of the first chancre, and also during the tertiary period. He concludes that immunity is complete only during the secondary period, that it is incomplete during the primary period, and gradually weakens during the tertiary period.

It appears, therefore, that it is impossible to prove that an abortive cure of syphilis can be realised by arsenobenzol or any other drug.

2. The second question—whether arsenobenzol prevents tertiary and parasyphilitic lesions—need not detain us, for it would take many years to prove. It may be mentioned, however, that this point has been proved for mercury by Fournier's statistics,[4] so far as statistics can prove anything.

3. The third question is whether syphilitic lesions heal under arsenobenzol more rapidly, more constantly, and with less liability to relapse and recurrence than under mercury and iodides. Taking this question as a whole, the answer appears to be a negative one, although on certain points there are differences in the results of different observers.

As regards the rapidity and constancy of action, the earlier investigators described this as "marvellous," "miraculous," and even "dumbfounding." Obsessed by their enthusiasm for the new drug, they seemed to have forgotten that it is quite a common thing for syphilitic lesions to disappear with "marvellous" rapidity under mercury and iodides; indeed, before the discovery of the spirochæta pallida this rapidity of disappearance was often a source of embarrassment by obscuring the diagnosis, in cases of doubtful chancre, for instance.

I have before me photographs of two typical cases treated by arsenobenzol; one, a primary chancre which healed in eight days, the other an early secondary syphilide which mostly disappeared in two weeks. It is quite common for such lesions to heal in the same time under mercurial treatment, especially by inunction. Gottheil,[5] one of the most recent and more impartial observers, says: "Its immediate effect may be better, in some cases, than that of mercury; in others it is slower and less certain; in some cases it fails." Professor Gaucher,[6] who has recently published the results of his experience at the St. Louis Hospital, finds that there are some cases which resist the action of arsenobenzol; others which heal with the same rapidity as under mercury; others, again, which heal more rapidly, but the latter are superficial ulcers and mucous patches which are easily healed by mercury. Further, he finds that arsenobenzol has no effect on visceral syphilis, nor on parasyphilitic affections such as tabes, general paralysis, and lingual leucoplakia.

As regards liability to relapse and recurrence, the earliest reports did not mention these because they were published before relapses had time to occur. Very soon, however, relapses were noted, but were attributed to too small a dose. More recently relapses have been shown to be common after the average dose of 0·6 gramme.

I think it will appear obvious from the foregoing considerations that mercury cannot be replaced by arsenobenzol in the treatment of syphilis, at any rate in the present state of our knowledge. In fact, the so-called "treatment of syphilis by '606'" is a misnomer, it is really the treatment of certain symptoms of syphilis, not treatment of the disease itself.

The next point to consider is whether arsenobenzol is of use as an alternative drug, more especially in cases where mercury fails. It is in the latter class of case that Gaucher[7] thinks it chiefly useful, but not always, for he has seen lesions which resisted the action of both mercury and arsenobenzol. As regards these cases which are said to be resistant to the action of mercury, as Gaucher remarks, they are very rare. In my experience there are few lesions of primary, secondary, or tertiary syphilis which cannot be healed by judicious combinations and variations of mercurial and iodide treatment. I think the failure is more often due to the method of administration than to the drug itself or to any idiosyncrasy in the patient. Failure is often due to the adoption of routine methods. One of the most intractable cases of tertiary syphilis I ever saw was healed by small doses of potassium iodide (5 grains) given in large quantities of hot water. This case, which had resisted all the usual methods of mercurial and iodide medication, is mentioned by Mr. A. H. Ward.[8] It shows what can be done by varying the doses and methods of administration of the time-honoured drugs. It appears, therefore, that if arsenobenzol has certain indications as an alternative form of treatment, these indications are extremely limited.

Lastly, we have to consider the toxic effects and possible dangers of this drug. In the first place, several deaths have occurred after its injection; some of these appear to have been directly due to the drug; while others, if not entirely attributable to it, were probably accelerated thereby. The method of intravenous injection seems to be specially dangerous, and requires considerable dilution of the preparation. Hutchinson[9] mentions a case of primary chancre in a healthy woman which almost terminated fatally after an

intravenous injection, and he remarks that "the intravenous injection of '606,' if adopted to any considerable extent, will certainly be followed by a number of deaths directly the result of such injections."

It may be remarked that fatal results have also occurred in connexion with mercurial treatment, but these have mostly followed the injection of insoluble preparations, especially grey oil. The danger of insoluble preparations applies equally to mercury and arsenic; a deposit of the drug in the tissues may suddenly give rise to intense and uncontrollable intoxication. Here it is the method which is at fault, not the drug. There are other ways of giving mercury which are free from such dangers.

Among other untoward effects of arsenobenzol may be mentioned necrosis of the tissues after intramuscular injections, and irritation of the kidneys (Gottheil). It is said that arsenobenzol is free from the danger of causing optic atrophy, a disaster which led to the abandonment of atoxyl and arsacetin; but it is difficult to be satisfied that no such danger exists, especially in subjects who are susceptible to arsenic. In fact, according to Isaac,[10] two cases of blindness have been reported.

To sum up, when we take into consideration the failures and limitations of arsenobenzol, the possible dangers and disasters which may follow its use, and the elaborate precautions necessary for its preparation and administration, it appears evident that if mercury is ever to be supplanted by another drug, arsenical or other, it is not by arsenobenzol, at any rate in its present form. It would have been better both for the profession and the public if some of the workers in this field had been a little more level-headed and a little less precipitate. Hata himself is more reserved and limits himself to the statement that, if not capable of effecting a clinical cure, "606" may ultimately lead to the discovery of a specific treatment for spirochætal diseases.[11]

*Conclusions.*

1. In the present state of our knowledge there is no drug which can replace mercury in the treatment of syphilis.
2. Although arsenobenzol causes rapid healing of certain syphilitic lesions, this effect is not constant and is often only temporary.
3. There is no proof that an abortive cure of syphilis can be realised by this drug.
4. If arsenobenzol is indicated at all in the treatment of syphilis, it is chiefly in those cases which are not influenced by mercury, but such cases are rare. Moreover, some cases resist the action of both drugs.
5. The administration of arsenobenzol is attended with many risks and dangers.

# CONTRIBUTIONS TO THE PHYSIOLOGY AND PATHOLOGY OF THE ASSIMILATION OF ALBUMIN.

BY S. A. ARANY, M.D.

*The Physiology of the Assimilation of Albumin.*

IN spite of various experiments on animals and *in vitro* the physiology of the assimilation of albumin is far from established, and our knowledge of the same only consists of theories founded upon these experiments. The majority of the authors suppose that the albumin of the ingested food, after having been rendered more accessible to the action of the ferments—i.e., the pepsin and trypsin—by the disintegrating action of the hydrochloric acid of the gastric juice, is decomposed into peptones, and the latter, through the united action of the trypsin and the enterokinase, into amino-acids. Although the components of the albumin just mentioned have been traced in the organs and the urine, several authors do not admit that the albumin is decomposed as far as into amino-acids, and claim that also larger (coarser) components may be assimilated by the system. Whatever the steps of decomposition may be, it is generally believed that the components of the albumin are united into so-called neutral albumin in the intestinal wall, and the former is conveyed by the blood to the various organs which transform it into tissue albumin. It is also supposed that the cells only avail themselves of such components of the neutral albumin as they need for their building up, the remaining components being excreted as urea, uric acid, &c., with the urine.

If, however, we compare the nitrogen of the albumin ingested with that which is excreted we find that both amounts are equal, from which fact it might be concluded that the albumin ingested only serves the purpose of replacing the tissue albumin decomposed by the system—viz., the cells can only assimilate such amount of albumin as corresponds to the amount of bodily albumin disintegrated by the cells. According to this view, the system is not able to assimilate albumin ingested in excess, and the excess ingested is only decomposed and excreted by the system. This is, however, as Abderhalden[1] rightly remarks, a gratuitous assertion, as we have no right to consider the nitrogenous substances only in estimating the amount of albumin assimilated by the system, but we are compelled to take also the other constituents of the albumin into consideration.

That the amount of eliminated nitrogen cannot be taken as a criterion in judging the amount of albumin assimilated by the system, I think is proved by the fact that in cases of grave diabetes the amount of the eliminated nitrogen is fairly normal, and still we find that the assimilation of albumin is greatly impaired. We find, namely, that in spite of the total restriction of carbohydrates and fat the urine contains, besides a normal or almost normal amount of nitrogenous substances, a large amount of glucose, which latter undoubtedly originates from the albumin ingested. It is not doubted by any physiologist that glucose is derivable from albumin, but how this process is performed is not established as yet.

However, even if we do admit that the elimination of glucose with the urine on a purely albuminous diet is a pathological symptom, we need not run away with the idea that the formation of sugar from albuminous matter is a pathological process. On the contrary, we are entitled to conclude that a certain part of the ingested albumin is, or rather that certain constituents of it are, also under normal conditions turned into glucose which the system either uses as energy or stores up as glycogen. There is nothing to prevent us from supposing that certain constituents of the albumin are converted into glucose which becomes united with the nitrogenous constituents of the albumin into neutral albumin; there is also no doubt that albumin if ingested in excess is not entirely eliminated from the system, as under normal conditions only the nitrogenous constituents are traceable in the urine, in the latter being no trace of sugar, which makes it evident that the carbohydrate constituent of the excess has been retained—i.e., either utilised or stored up by the system. The normal process of the assimilation of albumin is, therefore, likely to occur in the following way.

After the hydrochloric acid has loosened the structure of the albumin it is converted by the pepsin into its derivatives, the peptones, which latter are decomposed into their smaller constituents by the ferments of the pancreas and intestinal juice. The majority of authors presume that in this latter process only the trypsin of the pancreas and the erepsin of the intestinal juice take part, by the action of which the peptones are decomposed into amino-acids. In favour of this supposition there are only the experiments performed *in vitro* with albumin and above-mentioned ferments, resulting in amino-acids having been found as final products. This, however, cannot be looked upon as an unmistakable proof that the assimilation of albumin in the system takes the same course, and does not exclude the possibility that besides the fermentative processes mentioned some other processes may take place as well, by which some constituents of the albumin are converted into glucose. The ferment necessary for this process may be provided by the pancreas, and intermediary products of albumin into carbohydrates are also to be found in the system, as it cannot be denied that glucosamine is a representative of such intermediary products. Thus, aminohexose, the chemical composition of which differs very little from that of glucose, as only one molecule of OH is replaced in it by a molecule of $NH_2$, is to be considered as an amino-sugar, and is very likely only a representative of a great class of

[1] E. Abderhalden: Lehrbuch der Physiologischen Chemie.

nitrogenous carbohydrates, which, so far, have not been isolated. That nitrogenous carbohydrates can be converted into non-nitrogenous ones is evidenced by Langstein's[2] experiments, that author having succeeded in obtaining from serum-globulin, glucosamine as well as glucose.

It is perhaps Pavy's[3] greatest achievement that he first called attention to the fact that almost every kind of albumin contains a carbohydrate constituent, and he succeeded in obtaining carbohydrate from protein by the breaking-down action of both potash and sulphuric acid, the product in the former case presenting itself in the amylose form and in the latter as sugar. Pavy also investigated the various kinds of albumin, and found that the albumin and vitellin of the egg, the proteins of the blood serum and the fibrin, as well as the gluten of wheat and the protein of the haricot bean, contain a considerable amount, whereas casein contains an insignificant amount of carbohydrates. Pavy concludes from his investigations that the presence of carbohydrates in the albumin is due to the circumstance that sugar as such cannot reach the circulation, but it has to undergo some changes previously to its entering the blood. This change takes place, according to Pavy, at the seat of absorption—i.e., in the mucous membrane of the intestine, where there is an active growth of lymphocytes carried on in concurrence with the absorption of the products of digestion. The lymphocytes take to themselves molecules of suitable configuration for being linked on to them, and thus also the sugar molecules become built into a newly formed chemical complex, which is then carried into the circulatory system.

As I have already pointed out in my article on the Assimilation of Carbohydrates in Health and Disease,[4] Pavy's theory does not suffice to account for the assimilation of all the carbohydrates ingested, because we know on the one hand, that the amount of glycogen contained by the system is about 300 grammes, which would only account for a very small part of the carbohydrates ingested; on the other hand, albumins contain, even in the case of all of their constituents not being known, much too little carbohydrate to account for the large amount of carbohydrate assimilated by the system; and it seems more likely, as I pointed out in my above-mentioned article, that that part of the carbohydrate which is not turned into glycogen is converted into fat. Although we cannot accept Pavy's theory in the sense suggested by him, it will give us some useful information regarding the assimilation of albumin. As mentioned before, the ingested albumin is decomposed into its constituents by means of ferments, and it is very likely that this process is performed by the pepsin, trypsin, and erepsin, as well as by means of some diastatic ferment, most likely supplied by the pancreas, which diastatic ferment converts the nitrogenous carbohydrates into glucose. The constituents of the albumin are united into neutral albumin in the intestinal wall, wherefrom this latter product is conveyed by the blood to the various organs in order to be transformed into tissue albumin. It is obvious that this latter process cannot be uniform, as the tissues of the various organs are different, and therefore the cells only avail themselves of such constituents of the neutral albumin as they may be in need of; and thus those cells the albumin of which contains a larger amount of carbohydrates will most certainly avail themselves of the whole amount of carbohydrates contained by the neutral albumin, whereas the cells containing a smaller amount of carbohydrates will utilise only a part of this substance, the remainder being stored up as glycogen.

Besides the glucosamine there are the carbohydrates contained by the nucleo-proteins at the disposition of the system, as it is a well-known fact that these compound albumins contain, besides albumin and nucleinic acid, some carbohydrates belonging to the pentose group. These carbohydrates were first isolated from the nucleo-proteins of the pancreas and were described by Neuberg[5] as xylose. It is obvious that the nucleo-proteins are decomposed into their constituents in the same way as the other albumins, after which process the constituents are united into neutral albumin and conveyed to the organs in order to be assimilated into bodily nucleo-proteins.

Should the albumin ingested contain an insufficient amount of carbohydrates the constituents of the decomposed albumin will have to be supplemented by the carbohydrates ingested, in which case the synthesis described by Pavy may take place, but as long as the ingested albumin contains all the constituents of which the neutral albumin is to be formed the system will not be required to draw from the carbohydrates ingested. It follows, therefore, that the ingested albumin is decomposed into its nitrogenous constituents—i.e., the amino-acids—as well as into its carbohydrate components, and both kinds of constituents are united into neutral albumin by the action of the intestinal wall. The neutral albumin, which is to be considered the parent substance of the tissue albumin, is conveyed by the blood to the cells of the various organs, which transform it into their respective tissues. The circumstance that the amount of nitrogen ingested corresponds to the amount of nitrogen eliminated led to the belief that the system can only utilise such amount of the albumin ingested as corresponds to the amount of tissue albumin disintegrated. This may be correct as far as the nitrogenous substances of the albumin are concerned, but does not apply to the carbohydrate component of the albumin, as this latter is utilised in the same way as the carbohydrates ingested—i.e., as energy and reserve material. It is also likely that the reserve material thus formed is utilised in case the albumin ingested contains too little carbohydrate components. The formation of glucose from albuminous matter is, therefore, to be looked upon as a physiological process, but it must be borne in mind that the sugar thus formed is only a transitory product which *in statu nascendi* becomes combined with the nitrogenous constituents of the albumin into neutral albumin.

*Pathological Conditions.*

Under pathological conditions—i.e., in the grave and very grave forms of diabetes—we find that even on a purely albuminous diet glucose appears in the urine, from which we may conclude that the assimilation of albuminous matter is impaired. If we consider in such cases the nitrogenous final products of the albumin in the urine, we find them to be either normal or very little different from normal, from which we may conclude that the assimilation of the nitrogenous portion of the albumin is not interfered with, whereas the utilisation of the carbohydrate portion of the albumin is not effected in the usual way. The deviation from the normal process taking place in diabetes could be ascribed to the circumstance that the glucose formed from the albumin is not being combined with the nitrogenous constituents into neutral albumin. This process is under normal conditions very probably effected by means of some ferment, which is either insufficiently or not at all present in diabetes, owing to which glucose is liberated and eliminated by the urine.

It may also be supposed, however, that the formation of neutral albumin takes its normal course in diabetes, and that the former, after having been conveyed to the cells and decomposed by them, cannot be converted into tissue albumin, owing to the lack of a ferment, which under normal conditions unites the glucose and the amino-acids into tissue albumin. In this case we have to deal with an impaired activity of the cells, preventing the amino-acids from being combined with the glucose, which latter thus liberated makes its appearance in the urine. The diabetic system can either partly or totally lose its ability to combine the constituents of the decomposed albumin into neutral and tissue albumin respectively. The former—i.e., the partial loss of this ability—is observed in cases of medium gravity, which very often are only due to an excessive ingestion of albumin, and easily improve by the reduction of the latter. In these cases the cells of the intestinal wall or other bodily cells have very likely too little ferment at their disposal, and therefore cannot combine all the glucose and amino-acids into neutral and tissue albumin respectively, which circumstance gives rise to glycosuria. However, if we reduce the amount of albumin ingested the constituents will have plenty of ferment at their disposal to perform the physiological process and the glycosuria will disappear. In very grave cases of diabetes there is either very little or no ferment present, as the reduction of the albumin ingested has no appreciable effect upon the glycosuria, and it is very likely

[5] Carl Neuberg: Die Konstitution des Pankreas-proteïd, Berichte der Deutschen Chemischen Gesellschaft, 1902.

that at this stage of the disease all the sugar derived from the albumin ingested escapes assimilation and appears in the urine. The nitrogenous constituents of the albumin endeavour, however, to find some compensation for the loss thus sustained, and have recourse to the tissue albumin in order to extract the glucose of the latter. This endeavour, which may be looked upon as "tissue hunger," entails a considerable breaking down of body tissues and involves the patient in the greatest danger.

*Acidosis.*

The breaking down of body tissues does not only bring about impoverishment of tissues, but also acidosis, which is caused by the abnormal or rather perverse decomposition of body tissues, which process gives rise to the formation of acetone bodies.

Some authors claim that the acetone bodies do not originate from albumin. Magnus-Levy [6] found in a case of diabetic coma 342 grammes of acetone bodies in the urine in the course of three days, although only 311 grammes could have been formed of the albumin decomposed in that space of time, and therefore he thinks that the source of acetone bodies is fat. This, however, cannot be accepted as proof that the acetone bodies do not originate from albumin, as first of all it must be remembered that the acetone bodies are formed by the breaking down of body tissues and not by the decomposition of the albumin ingested; and, on the other hand, it has not been proved that the albumin must be decomposed into its usual final products for the purpose of yielding acetone bodies.

It cannot be denied, however, that fat may be the source of acetone bodies, as many experiments have shown that the administration of fat, and especially of butter, increases the acidosis in grave cases of diabetes; and it is very likely that the breaking down of body tissues involves, besides the albumin, the fat as well. It is also likely that by the breaking down of fat not only acetone bodies but also glucose is formed, for the reverse process occurs under normal conditions, and the diabetic system, as I pointed out elsewhere,[7] destroys where the normal system builds up.

Although it may also be concluded from various processes of assimilation that all the energy liberated in the animal system is due to the carbohydrates, and only these can be looked upon as the source of energy, it is the grave form of diabetes which best proves the correctness of this supposition. We know that in the mild or alimentary form of diabetes a certain part of the carbohydrates ingested is utilised by the system, but with the increasing intensity of the disease the system loses even this reduced tolerance of carbohydrates, and tries to make good the deficiency by using some of the carbohydrates of the albumin as energy, in which it succeeds only for a certain length of time, as the system sooner or later gets deprived of the ability of combining the constituents of the decomposed albumin, which gives rise to the escaping of glucose. Thus the system is deprived, not only of energy, but also of a very important constituent needed for its building-up process, and, therefore, in order to satisfy its want, disintegrates its own tissues.

The majority of authors suppose that the formation of sugar from albumin is effected by a very complicated synthesis, as the amount of carbohydrates contained by the albumin is, according to these authors, too small to account for the large quantities of glucose eliminated in the grave form of diabetes. But the amount of the carbohydrates in albumin is usually judged by the amount of glucosamine contained in it—a judgment to which we are not entitled, for the circumstance that so far only this aminohexose has been isolated from albumin does not necessarily prove that there are no other carbohydrates present in it. Besides, it must be borne in mind that the nucleo-proteins also contain a carbohydrate constituent, and even if this latter belongs to the pentose group, it is very likely that it is converted by the system into glucose, as Lindemann and May [8] produced glycosuria of several days' duration in a diabetic patient who had been free from sugar for a certain length of time by the administration of pentose. It is therefore unnecessary to presume a complicated synthesis of sugar from albumin in diabetes, as we have seen that almost every kind of albuminous matter contains a carbohydrate constituent, and therefore it is far more reasonable to suppose that the formation of glucose from albumin is effected by decomposition and not by synthesis.

The large amount of glucose eliminated in the grave form of diabetes is, however, not only derived from the albumin ingested, as mentioned above, but fat must also be considered a possible source of glucose, and there is no doubt that the breaking down of body tissues also contributes towards the increase of the amount of glucose eliminated by the diabetic.

Diabetes has, therefore, to be considered as a progressive malady of assimilation in general, conditioned by the loss of assimilation of the carbohydrates. The latter ensures with the increasing intensity of the disease the degeneration of all the processes of assimilation, as the system endeavours to convert all the foodstuffs ingested into glucose, which latter it can neither use as energy nor lock up as body tissues, whereby both loss of energy and impoverishment of body tissues take place. The impoverishment of body tissues becomes increased by the circumstance that the system finally avails itself of its own tissues in order to accomplish its perverse processes of assimilation, thus further disturbing the balance of assimilation.

The assimilation of carbohydrates must, therefore, be considered the nucleus of all assimilative processes, for the latter, as we have seen, entirely depend on the former. If there is nothing to interfere with the assimilation of carbohydrates, the system will not only be the recipient of all the energy necessary for its vital functions, but will also be in a position to store up a part of the assimilated carbohydrates as glycogen and fat. The normal assimilation of carbohydrates, however, also affects the assimilation of albumin, the former being looked upon as albumin sparing, owing to which quality a smaller amount of bodily albumin gets decomposed, and therefore, also, a smaller amount of the albumin ingested will have to be used for the building-up process, and the excess of the ingested albumin may become transformed into reserve material.

On the other hand, if there is something wrong in the assimilation of carbohydrates, the albumin ingested will have to replace the vital functions of the carbohydrates, in which case the system will be deprived of the albumin-sparing quality of the carbohydrates, but it will not be entirely deprived of energy, as the albumin ingested replaces the carbohydrates to a certain extent. With the increasing intensity of the disease the system loses the ability to use the glucose derived from albumin as energy or to lock it up as body tissues, and in the end has recourse to its own tissues. Although diabetes shows us what an important part the carbohydrates take in the processes of assimilation, it does not give us any evidence of the normal process of assimilation of the carbohydrates, and all we know of the latter is only based upon more or less likely theories. I described my own views of the assimilation of the carbohydrates in my work, which I have already mentioned, and since that also on other occasions,[9] and shall only allude to the matter as far as the explanation of the present subject may require it.

We know that the system contains about 300 grammes of glycogen, which accounts only for a very small part of the carbohydrates ingested, and therefore the question arises, What becomes of the greater part of the carbohydrates not converted into glycogen? The experiment with Eck's fistula has shown us that the ingestion of sugar as such causes glycosuria, whereas the ingestion of amylaceous food does not give rise to glycosuria in animals whose liver is cut out of the circuit, which fact leads me to the conclusion that the sugar ingested as such is differently utilised from the sugar derived from starchy food, the former being conveyed to the liver in order to be converted into glycogen, whereas the latter must be converted into some other material, as we have seen in the above experiment that only the assimilation of sugar ingested was interfered with.

If we take into consideration that animals whose food principally consists of carbohydrates have got the largest panniculus, it appears to be obvious that the part of the carbohydrates which is not converted into glycogen is

converted into fat. That carbohydrates can be converted into fat is evidenced by the fact that unripe linseed[10] contains a great deal of carbohydrate and no oil, whereas after coming to maturity the seed shows just the reverse proportions—viz., it contains no carbohydrate and a great deal of oil. It is therefore more than likely that an analogous process occurs in the case of the assimilation of starchy food, and this process must evidently occur in the intestine, as is evidenced by the experiment with Eck's fistula, in which the ingestion of amylaceous food was not followed by glycosuria, which admits the conclusion that the sugar must have been transformed somewhere before it entered the blood—viz., in the intestine.

It is impossible to state how the conversion of starch into fat is effected and what chemical changes the starch undergoes until its conversion into fat, as we do not yet know the intermediary products of the latter. However, it seems to me very likely that this process is being performed by the coöperation of the pancreas and the intestine, a similar coöperation being claimed for the assimilation of albumin, in which process the trypsin is supplemented in its action by the intestinal juice—viz., by one of its ingredients named enterokinase. We also know that the intestinal juice obtains some substances from the bacteria of the intestines, which substances may activate certain enzymes or may independently perform some assimilative functions. Such coöperation of the intestinal flora may take place in the conversion of the components of starch into fat, which process may be looked upon as a symbiosis—i.e., a joint action of the intestinal flora and the intestinal cells.

It is a well-known fact that under favourable circumstances certain bacteria produce some substances which are useful to the system; should, however, the circumstances change and become unfavourable to the bacteria the latter will not only not produce the useful substance, but will attain the ability to produce substances detrimental to the system—i.e., toxins. It is also known that in the grave form of diabetes even the total restriction of carbohydrates and the administration of a diet consisting of albumin and fat do not prevent the glycosuria, and it is, therefore, very likely that the vital conditions of the bacteria supplying the substance necessary for the conversion of sugar into fat have become unfavourable, and therefore the bacteria, instead of producing the substance necessary for the physiological process, produce a toxin possessing the ability to convert the fat ingested into sugar. Should this toxin attain a greater virulence it will very likely possess the ability to interfere with the activity of ferments, and thus it may also interfere with the ferment combining the decomposed albumin into neutral and tissue albumin respectively, by which interference the carbohydrate component of the albumin gets liberated and escapes with the urine. At the height of its virulence the toxin gives rise to breaking down of body tissues, which not only causes glycosuria but also the appearance of organic acids in the blood, which latter are due to the abnormal—i.e., perverse—decomposition of body tissues. In the formation of these acids also the fat participates, but I should leave it undecided whether the toxic symptoms in diabetic coma are only due to the presence of the acetone bodies, or are caused by the toxin itself.

Having now arrived at the end of our reflections with regard to the physiological and pathological processes of assimilation of albumin, I think that the only fault to be found with them is their hypothetical basis, as in the chain of deduction of the various assimilative processes depending one on another there is no link missing, which circumstance in itself speaks also for the correctness of the hypothesis.

In conclusion, it may be added that since certain ferments, or at least their actions, are known, some assimilative processes are performable also outside of the system, and there can be no doubt that other processes of assimilation are dependent upon the presence, or rather upon the activity of bacteria, as is proved by Schottelius's experience, who found that chickens put upon sterilised food did not develop and soon succumbed, whereas if bacteria were added to their food they soon recovered and prospered. Another striking proof of the action of bacteria upon the assimilation is afforded by the researches of Ellenberger, who discovered that boiled or filtered intestinal juice of the horse lost its ability of dissolving cellulose.

The physiologist as well as the pathologist has therefore, in order to establish the normal and pathological processes of assimilation, to work in the same direction, this being the careful study of the bacteria living in the system, by the knowledge of which not only physiology and pathology but also therapy will be put on the right track.

## A CASE OF SO-CALLED "INSUSCEPTIBILITY TO VACCINATION."

BY J. D. STAPLE, M.R.C.S. ENG.,
PUBLIC VACCINATOR FOR THE ASHLEY DISTRICT, BRISTOL UNION.

I WAS recently asked to vaccinate a boy aged 4½ years. The father informed me that when an infant the child had been vaccinated three times unsuccessfully, the operation being performed on each occasion in one mark. He added that a certificate of insusceptibility to vaccination had been sent to the vaccination officer. The man further said that he had recently "been studying vaccination," and having his doubts as to the efficacy of "one-mark vaccination," was anxious to have the child vaccinated again. I vaccinated the child, and on inspection the result was satisfactory. The vaccination officer corroborated the statement as to having received the certificate of insusceptibility to vaccination.

In Bristol during 1909 and 1910 the successful number of primary vaccinations was about 9000; of this number more than half were performed by the public vaccinators. Twenty-six cases of insusceptibility to vaccination were notified during the two years, but none of these were reported by public vaccinators.

It is perfectly obvious that if a child is vaccinated in only one mark there is less likelihood of the operation being successful than if it were performed in the orthodox number of places. It is to be regretted that when a certificate of insusceptibility is filled up the practitioner is not required to certify that the child has been unsuccessfully vaccinated in three or four marks on three separate occasions; we should then have a perceptible decrease in the number of insusceptible cases.

It is a very unsatisfactory state of things that a one-mark vaccination can be called a successful vaccination. All the authorities on vaccination strongly condemn such a practice, and yet there are a few practitioners in large cities who vaccinate a very large number of infants in one mark, parents even bringing their children from outlying country districts to them for the purpose. It is perhaps too optimistic to hope that for the present, at any rate, there will be the slightest improvement in the vaccination laws. Vaccination is rapidly diminishing, conscientious objection certificates are most readily obtained (in Gloucester they nearly double the number of vaccinations), and if the parents should be summoned the magistrates generally inflict a fine of 1*s.*, and parents who prefer a modified form of vaccination can generally find a practitioner who, for "a minimum fee," will perform a small "one-mark vaccination."

Bristol.

THE FINANCIAL POSITION OF THE TIVERTON INFIRMARY AND DISPENSARY. — The committee of the Tiverton (Devon) Infirmary and Dispensary in its annual report for 1910 states that an adverse balance of £252 exists against the institution. The committee adds that unless the income is increased the infirmary must be used for accidents only. The existing dispensary would still be continued. A commissioner recently inquired into the endowed charities of Tiverton, and it was proposed that some of the funds derived from these sources might be given as annual donations to the infirmary. The Tiverton Infirmary was founded in 1868 and contains 23 beds. Subscriptions have been received in consequence of this appeal, and it is hoped that a sum of money will shortly be subscribed sufficient to place the charity in a sound financial position, so that the committee will have no necessity for curtailing the useful work of the institution.

## MEDICAL SOCIETY OF LONDON.

*Malignant Stricture of the Œsophagus.*

A MEETING of this society was held on Feb. 13th, Mr. CHARTERS J. SYMONDS, the President, being in the chair.

Dr. G. WILLIAM HILL demonstrated on patients the treatment of Malignant Stricture of the Œsophagus, with special reference to the employment of intubation and of radium. He said that the treatment of primary gullet cancer was practically nearly always merely palliative for the relief of dysphagia and pain. The only cases in which operation had hitherto been successful were in all probability not instances of primary disease in the œsophagus, but of invasion, cancer from the pharynx, and in these instances Solis Cohen's and Gluck's types of operation—viz., total laryngectomy, together with partial excision of the deep pharynx and of a small segment of the adjacent cervical œsophagus—had often been successful. Œsophagectomy alone, whether of the cervical œsophagus as first practised by Czerny, or of the thoracic, or of the abdomino-thoracic œsophagus by thoracicotomy after the methods of Sauerbruch, von Hacker, W. Meyer, and others, had no permanent or even temporary cure to its credit. With early recognition by means of the more general adoption of exact endoscopic methods of diagnosis, together with improvements in operative technique, an occasional successful œsophagectomy might be regarded as a matter of time, but that time was not yet. Killian had claimed to have diagnosed and successfully removed a small sarcoma of the gullet by endo-œsophageal measures through the œsophagoscope, but it would probably be long before another such cure was recorded. The only external operative treatment which had been, and was still, extensively practised was the strictly palliative operation of gastrostomy, but Dr. Hill thought he would be able to show that the endo-œsophageal palliative measures mentioned in the title of his paper—viz., intubation and radium—would in the near future render the necessity of the resorting to gastrostomy a much more exceptional event than it was to-day. Before dealing in detail with these special procedures with radium and intubation he passed under rapid review such palliative measures as treatment by drugs—e.g., iodides, iodipin, fibrolysin, which, like serum therapy, were not often even of temporary value. Of drugs acting locally spirit of ether broke up frothy mucus in the gullet by reducing surface tension; astringents, like adrenalin, cocaine, and turpentine, were of little use; local anodynes, like morphia, chloretone, and orthoform, were sometimes useful for pain in cancer high up; they rarely, however, enabled one to dispense with hypodermic injections of morphia, atropine, &c., in very painful cases. Lavage of the gullet in cases of dilatation above a stricture was the best means of removing decomposing substances, but glycerine of boric acid and of carbolic acid, sanitas, and similar preparations were also useful as disinfectants and deodorants. Peroxide of hydrogen was contra-indicated. Caustics were generally inadvisable, even when applied endoscopically to tight strictures; and electrolysis, ionisation, and carbon-dioxide snow had not as yet had any extensive trial. Relief of dysphagia by the X rays had been claimed in a few instances where the disease was high up. The question of diet was of great importance, but time did not admit of its proper discussion on this occasion. Blind bougieing undoubtedly gave relief to dysphagia, but was not free from danger even in expert hands, and should be abandoned in favour of endoscopic bougieing which was a much safer and more efficient procedure in every way; but with intubation periodical bougieing was unnecessary. The permanent retention of a small gum elastic oro-œsophageal catheter or feeding tube had been advocated by Krishaber at the International Medical Congress in London in 1881. Mackenzie was the first to use an entirely intra-œsophageal permanent intubation-tube of gum elastic held in position by strings. This was later superseded by Symonds's gum elastic intra-œsophageal funnel, an appliance of great utility which could, by the aid of the œsophagoscope, be much more easily inserted than formerly. When the stricture could not be sufficiently dilated by endoscopic graduated bougies or when it was near either end of the gullet, Symonds's funnels were impracticable. James Berry was the first to employ permanent soft red rubber oro-œsophageal tubes of small calibre, which were, however, difficult of introduction. Symonds improved on Berry's method by introducing a red rubber oro-œsophageal catheter shaped like a Jacques urethral catheter, which was more easily introduced by a whalebone guide inserted into the eye near the distal extremity. This method had proved most useful in his (Dr. Hill's) hands, but the pliant tube was liable either to be vomited or coughed up, and could only be reintroduced by one skilled in its use without the aid of the œsophagoscope. Dr. Hill had therefore been led to devise a styletted red rubber oro-œsophageal catheter for either permanent or temporary retention, which by reason of its having a backbone of soft silver or of whalebone fastened to the teeth was not easily ejected by the severest coughing or vomiting. Patients could be fed with liquids through the tube, and after this intubation apparatus had been worn a week or two the dilating bougie effect often enabled the patient to swallow fluids, soft food, and often some solids by the side of the tube. Although in advanced cases the styletted tube had to be retained *in situ* permanently, in others it could be left in for a week or two until from the bougie effect the patient swallowed well by the side of the tube when it could be removed until the dysphagia again became troublesome. He had treated a large number of cases by either the permanent or the temporary wearing of this styletted oro-œsophageal intubation tube with the most gratifying results; the tube was well borne and Dr. Hill regarded gastrostomy as nearly a thing of the past in his practice. The styletted tube was not only more efficient than other intubation tubes, but it was more easily introduced than any other with or without endoscopic bougieing. Moreover, feeding entirely through an oro-œsophageal intubation tube was specially indicated for permanent use where there was a communication between the malignant gullet and the air passages, so that liquid nourishment could be poured directly into the stomach. Several *confrères* had adopted that method of treating dysphagia for stricture with complete satisfaction. It was indicated in cases which were unsuitable for the employment of Symonds's funnel. The life of the styletted tube was from five to ten weeks. Dr. Hill then spoke of the employment of radium. Impressed by the results claimed abroad by Exner, Einhorn, Goisey, and others in gullet cancer, he stated that he was the first to apply radium to the gullet in this country, and was probably the only one who had done much work on that viscus with large quantities of radium. He worked in coöperation with Dr. N. S. Finzi, who possessed 205 milligrammes of radium (costing £3300). They had treated 22 cases in all, using from 50 to 20 milligrammes on the gullet for periods varying from 12 to 28 hours on end, repeated in some instances as many as six times. They claimed four temporary cures; in six other cases there was quite remarkable improvement; in seven further cases there was substantial improvement; and in five cases only was there no improvement whatever, radium being only used once, and it was doubtful whether two of these cases (advanced ones) were not worse after the one application. The technique was explained and the subject generally was illustrated by a large number of X ray photographs and original drawings with the aid of the epidiascope; six patients were examined with the œsophagoscope, and the interior of the stomach in one instance was demonstrated by the new Hill-Herschell method of œsophago-gastroscopy, nearly everyone present being given an opportunity of seeing the region of the pylorus.

Dr. STCLAIR THOMSON gave details of the cases of two patients who had been much relieved by Dr. Hill's treatment.

Mr. L. B. RAWLING gave his reasons for preferring gastrostomy to other methods of treatment.

Mr. H. TILLEY said that when an anæsthetic was required for endoscopy of the œsophagus chloroform was better than ether.

Dr. FINZI said the dose of radium for healthy mucous membrane was 100 milligrammes for six or seven hours with a platinum shield 1½ millimetres thick, and for diseased membrane three or four times longer.

## MIDLAND MEDICAL SOCIETY.

*Exhibition of Cases and Specimens.*

A MEETING of this society was held on Feb. 1st at the Medical Institute, Birmingham, Mr. W. F. HASLAM, the President, being in the chair.

Mr. GEORGE HEATON showed a girl, aged 7 years, with severe Rickets, and also radiograms of her pelvis, spine, and other bones. The girl was only 34 inches high. She had extreme lordosis of her lumbar spine, and had the gait of a patient with congenital dislocation of the hips. There was marked double coxa vara, the great trochanters being on a higher level than the iliac spine, and movements of rotation inwards and abduction of the thighs were very limited. The radiograms showed that the neck of the femur on each side was horizontal and curved with a convexity forward. The pelvis, as shown in the radiogram, was extremely oblique and of the malacosteon or triradiate variety, both acetabula being driven inwards by the weight of the body acting on the heads of the femora. Two other children of the same family were the subjects of rickets.

Mr. C. A. LEEDHAM-GREEN showed three Papillomata of the Bladder which he had successfully removed. He also showed a young girl, aged 15 years, suffering from marked Acromegaly. The patient was first noticed to be growing abnormally fast in her ninth year, and is now, although with marked dorsal curvature, 6 feet 6¾ inches in height. Her face, hands, and feet showed the characteristic changes. A radiograph taken of the skull indicated an abnormally large sella turcica, but there were no ocular symptoms pointing to intracranial pressure. The question of operative interference by removal of the pituitary body was raised, but the patient's relatives decided against it.

Mr. BERNARD J. WARD showed two cases of Trigeminal Neuralgia cured by injections of alcohol. Both were men, one aged 34 and the other 67 years, and both were examples of epileptiform neuralgia in its worst form. In each case medical treatment of various kinds had been tried for over two years but without relief, even opium failing in the one case. The attacks of pain used to come on from 20 to 30 times a day, and were started by such a slight stimulus as a cold draught or eating, so that in one case liquids only could be taken. In both cases the second division of the fifth nerve was alone affected, and this was injected at the point at which it leaves the foramen rotundum with 2 c.c. of 80 per cent. alcohol containing some eucaine in solution. The first case had had no more pain since the fourth injection six weeks ago, and the second had been free from pain since the first injection, but it was thought better to give a second to guard against recurrence. He had been completely free from pain for two months.

Dr. C. E. PURSLOW showed: 1. Fibroids of the Uterus, with Bilateral Carcinoma of the Ovaries, removed by abdominal section. 2. A Fibroid of the Broad Ligament which was firmly impacted in the true pelvis. There had been incontinence of urine from overflow for several months, and the bladder at the time of operation reached to the umbilicus, though a catheter had been passed immediately before. The uterus bisected coronally was also shown, and a similar fibroid at an early stage of growth could be seen on the opposite side. 3. A Uterus with Large Submucous Fibroid removed by abdominal hysterectomy from a patient, aged 49 years, who had suffered from severe hæmorrhages for five years, and was very anæmic at the time of operation. One fibroid had undergone myxomatous degeneration. 4. A Uterus with Corporeal and Cervical Fibroids removed by abdominal pan-hysterectomy from a patient aged 46 years. Since her last confinement, five years previously, the patient had suffered from abdominal pain, menorrhagia, and frequent micturition.

Dr. WALTER R. JORDAN showed a girl, aged 2½ years, with an Abdominal Tumour, as a case for diagnosis. For some two months the mother had noticed enlargement of the abdomen, and declared that she could see an increase in the size each week. An apparently solid tumour occupied the entire left half of the abdomen and reached well over on to the right iliac region. The tumour had an irregular rounded edge anteriorly, and was lost posteriorly under the spinal muscles. The colon could be made out crossing it. Dr. Jordan regarded the case as one of renal sarcoma. No other opinion was expressed.

Mr. W. ARTHUR LOXTON showed two cases of Tertiary Syphilis which had been treated by subcutaneous injection of salvarsan. The emulsion for one case had been prepared thus: salvarsan, 0·6 gramme; absolute alcohol, 6 c.c.; hot water, 10 c.c.; normal sodium hydrate phenol-phthalein sol. 3 c.c.; and 3 drops of acetic acid to neutralise. Pain was so severe and so prolonged in all the cases in which this formula was adopted that its employment had been abandoned. In the second case the method of preparation adopted was that described by McDonagh. The bulk of injection was small, and if the procedure was properly carried out no pain was induced.

Mr. A. W. NUTHALL showed a specimen of Sarcoma of the Left Kidney taken from a female child aged 2 years. A tumour had been noticed for five months before death, which followed on progressive emaciation and weakness. The growth appeared to take origin at the upper pole of the left kidney and to be distinct from the renal tissue, a capsule intervening, but the upper portion of the kidney was distorted and replaced by the main mass of the tumour. Extending from the hilum of the left kidney were numbers of greatly enlarged retro-peritoneal glands, overlying the spine and reaching across to the right kidney and down into the hollow of the sacrum. A peculiar and unusual condition of the mesentery was present: it was solidly enlarged by masses of glands contiguous with and inseparable from the adjacent growth in the kidney; in this way the small intestine largely, and the descending colon altogether, were in front of the tumour. The right kidney was enlarged and hydronephrotic but not involved by the new growth. The left suprarenal capsule could not be found. The right suprarenal capsule was of normal size and shape.

## MEDICAL SOCIETY OF LIVERPOOL.

*The Use of Tuberculin in the Treatment of Phthisis.—Local Administrative Control of Tuberculosis.*

A MEETING of this society was held at the Medical Institution, Liverpool, on Feb. 9th, Dr. T. R. BRADSHAW, the President, being in the chair.

Dr. H. H. CLARKE read a paper on the Use of Tuberculin in the Treatment of Phthisis. He stated that at the Hospital for Consumption he and his colleagues had given a great deal of attention to this method of treatment and had published their results in various journals. He gave a short account of the plan of treatment he adopted; when dealing with patients who were inside the hospital he gave a course for 42 days, starting with 1-5000th c.c. of the original solution of the bacillary emulsion as prepared by Meister Lucius and Brüning. For the first ten days the dose was doubled each day, thus 4-50th c.c. was soon reached; this was again doubled on the twelfth, twentieth, thirtieth, and forty-second days. If the patient had to be treated in the out-patient department he gave a weekly dose of 1-500th c.c. He considered that the oral method was as useful as the hypodermic method of administration. He concluded that tuberculin was of use in the treatment of phthisis.

Dr. E. W. HOPE then read a paper on the Local Administrative Control of Tuberculosis. He pointed out the great difficulties which had in the past confronted the early attempts to deal with the prevention of tuberculosis due to the neglect in by-gone years of sanitary principles and to the large amount of unskilled and casual labour which had existed in Liverpool. He emphasised the view that efficient methods must begin at the control of the recognised disposing causes of tuberculosis, and showed by charts how the adoption of these methods had in Liverpool been crowned with success. When insanitary areas were first condemned the mortality from phthisis was 4 per 1000; in the last two years it had fallen to 1·9 per 1000. Dr. Hope exhibited models of the new and the old workmen's dwellings. Speaking of sanatoriums, he said that these must fail as great preventive means, whilst they had other uses. He gave an account of the sources of information at the disposal of the health authorities for the recognition and subsequent amelioration of tuberculosis, and considered that the various authorities now engaged in this work could with advantage be unified. He advocated as wise and economical the support of the dependents whilst the breadwinner was undergoing treatment, and considered that

accommodation for advanced cases and possibly the compulsory detention of dangerous cases were required. He estimated that the disappearance of phthisis would mean a saving to the nation of one-eleventh part of the total cost of pauperism—i.e., of £1,000,000 per annum. There was compulsory notification in the case of pauper consumptives, and he thought that this rule should be extended to all those who sought relief in any medical charity. Voluntary notification had worked well in Liverpool. Notwithstanding that the population of Liverpool had increased 115,000 from 1895 to 1910, the total number of deaths last year from phthisis was 3056 less than in 1895. Dr. Hope then gave an account of the German system of insurance for sickness, which he praised and said it deserved earnest attention.—Dr. W. PERMEWAN said that the radical cause of consumption was to be found in the housing condition of the people, and he paid a high tribute to the work that Dr. Hope had done in connexion with this problem. In view of the great prevalence of tuberculosis amongst barmen Dr. Permewan urged the necessity of the power of inspection by the health authorities. This they had not at present. The lighting and ventilation of public-houses were very often deficient.—Dr. NATHAN RAW favoured the prospect of unification of the authorities dealing with tuberculosis. He said that at the present time there were about 800 persons with phthisis mostly in an advanced stage under the care of the Poor-law and thus isolated. He was in favour of compulsory removal and detention of advanced cases. He looked forward to the time when the whole problem of the control of tuberculosis would be undertaken by the health authorities in each district.—Dr. J. J. BUCHAN, medical officer of health of St. Helens, urged the necessity of compulsory notification.—Dr. C. W. P. MOFFATT of Bolton said that in that town the poor people were recognising the infectivity of tuberculosis, and were compelling members of households suspected of suffering from that disease to attend the medical charities.

## ROYAL ACADEMY OF MEDICINE IN IRELAND.

### SECTION OF STATE MEDICINE.

*Medical Inspection of Schools and Scholars*

A MEETING of this section was held on Feb. 3rd, Professor E. J. MCWEENEY, the President, being in the chair.

Mr. J. B. STORY read a paper on Medical Inspection of Schools and Scholars, in which he advocated the extension of the recent Education Act to Ireland, more especially Section 13 of the Education (Administrative Provisions) Act of 1907, which compels all the local education authorities in England and Wales to appoint medical officers to inspect all elementary school children on admission and (as ordered by the Education Board) twice subsequently before leaving school. The medical officer has also to make an annual report to the local authority on the sanitary condition of the schools in his district, and the local authority has power to provide means of treating the curable maladies of the children infected subject to the approval of the Education Board. The educational arrangements in Ireland differ so much from those in England and Wales that the Act would, he said, require considerable modification before it could be applied to Ireland; but the necessity is urgent, as could be inferred from the report of the Dublin Sanitary Association recently published in the daily press. The Act referred solely to elementary schools, but Mr. Story contended that in Ireland the intermediate schools were very nearly as much in need of medical inspection as the national schools.

The PRESIDENT thought that medical inspectors for the schools should be introduced as soon as possible. He had often remarked the extreme frequency of vermin amongst the poorer classes, which vermin, he considered, gave entrance to staphylococcal infection.

Dr. J. H. P. BOYD BARRETT said that the Irish National Board had no power to spend its money on medical inspectors. He had read the report of a recent meeting at Paris, where representatives of all countries had assembled. This report showed the tremendous benefit which such countries as Germany, France, Russia, Holland, and even Mexico had derived from medical inspection of their schools. He laid great stress upon the fact that children were compelled to attend schools, yet no precaution was taken to prevent the spread of infectious diseases amongst them.

Dr. T. DONNELLY said that children or their guardians should be instructed as to the necessity for cleanliness. Mr. Story had shown the small amount of money that was necessary for medical inspectors, and if the matter was put fairly before the public he thought there would be no difficulty in getting a small rate.

Dr. T. P. C. KIRKPATRICK said that there was criminal negligence displayed in connexion with school children. He thought that if compulsory inspection was not adopted compulsory education should be stopped.

Sir JOHN MOORE said that 11 years ago he sat on the Local Government Commission to inquire into the health of Dublin. As one of the Commissioners it was his duty to visit the primary schools in Dublin. He then had no idea that such dirt and insanitary surroundings existed in their schools. The Commission made very strong recommendations which turned out to be practically a dead-letter. The Board of National Education was wrongly constituted. There should be a fair representation of medical men on the Board. It was most unfair that they should have no provision for safeguarding the condition of the children who went to the primary schools. These primary schools were hotbeds of infection, especially whooping-cough and measles, and neither of these diseases was notifiable.

Dr. R. B. MCVITTIE said a great deal had been said about infectious diseases which caused some benefit by giving immunity from these diseases in adult life. He did not consider them so serious as heart diseases. A number of children with feeble hearts were driven to school by a compulsory Act. If their object was to be gained, it was necessary for the medical profession to agitate persistently and constantly.

Dr. M. F. COX said that if the people did not move in the matter it was because they were ignorant. In America dirty children were not allowed into a public school.

Mr. STORY then replied.

DEVON AND EXETER MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held at the Royal Devon and Exeter Hospital on Feb. 10th, Mr. J. M. Ackland, the President, being in the chair.—Mr. C. E. W. Bell showed the following specimens: 1. Suppurating Gall-bladder, removed by operation, which formed a tumour descending well into the right lower abdomen and was greatly distended by several calculi. The patient made an excellent recovery. 2. Uterine Fibroid, partially extruded from the cervix uteri and removed per vaginam. 3. Vesical Calculus, removed by the suprapubic route from a man whose general condition made operation an anxiety, but who subsequently made a good recovery.—Mr. A. C. Roper showed specimens of: 1. Hydatidiform Mole, expelled naturally from a multipara, aged 41 years, who was admitted to hospital for severe hæmorrhage. The mass was delivered complete, a subsequent precautionary curetting by Mr. Roper revealing no further fragments. Sections by Dr. R. V. Solly showed no evidence of chorionic epithelioma. 2. Uterine Myoma (subperitoneal). The fibroid had become detached from the uterus and formed a tumour in the right lower abdomen. The woman was admitted to hospital with a history of recent peritonitis and for threatened bowel obstruction. Some difficulty was met with at operation owing to the omentum having curled itself round the tumour, which in turn lay in a bed of mesentery.—The specimens were discussed by Dr. J. D. Harris, Dr. G. P. D. Hawker, and Mr. G. E. A. Evans.—Dr. J. Shirley Steele Perkins reported a case of Renal Calculus in a woman aged 45 years. The case was remarkable for the small size of the stone and the definite diagnosis by means of a very clear skiagram, which, together with the calculus, was exhibited.—Dr. Harris and Mr. Roper discussed the case.—Mr. Roper reported two cases of Intestinal Obstruction, the first occurring in a young woman two weeks after confinement. The second case was that of a man aged 60 years. Obstruction appeared to be due to a small growth in the splenic flexure. Mr. Roper then read a paper entitled "Traumatic Neurasthenia and the Workmen's Compensation Act." He defined traumatic neurasthenia as "suspension, inhibition, or perversion of function resulting, without discoverable reason, from an accident or operation." Mr. Roper considered these cases to be rare and their extension from the leisured to the

labouring classes to be a matter deserving investigation. He illustrated his paper with notes on four cases under his personal care. Of these cases the actual injury in the first was of a very trivial nature, but vague neuralgic pain, diminution of field of vision in injured eye, flashes of light, together with restlessness and depression, followed. The man eventually compounded with his insurance company, gave way to drink, and became insane. In the second, a man, aged 30 years, received a severe cut at the junction of the cornea and sclerotic from a flake of red-hot metal. Removal of the eye was imperative, but recovery, as far as the wound was concerned, was in all ways satisfactory. This man became deeply depressed, but finally he recovered. In the third case a man, aged 43 years, had the ninth and tenth lower left ribs fractured through the backing of a cart against him. For many months there was vague neuralgic pain, at first thought to be due to exuberant callus, and a slight chiselling operation and electrical treatment gave no result. An exploratory laparotomy was then done, the symptoms suggesting the possibility of adhesions to some viscus. Nothing abnormal was detected, but the pain gradually disappeared; the man returned to work, and is now quite well. The last case was that of a man, aged 50 years, whose right eye was injured with a stick whilst he was hedge cutting. Some corneal opacity resulted, but otherwise the eye soon quieted down. Mr. Roper, in reporting his case to the insurance company, and suspecting neurasthenia would follow, advised one and a half year's total compensation to settle and get the man back to light work. The man, however, demurred, and was taken into hospital for further observation. Here he was found to have exaggerated reflexes, normal pupils, and a greatly reduced field of vision. He was advised to accept the company's offer and to return to light work. When told that worry about compensation had much to do with his symptoms, which were undoubtedly due to nerve and not to direct ocular defect, he admitted that his mind was never free, assented to a settlement, and returned to light work. Mr. Roper emphasised how frequent these cases had become since the passing of the new Act—inducing, as it did, greater introspection on the part of the labouring man than formerly and far more than was good for him. One must, however, separate this condition from that of the true malingerer. Work of some kind was undoubtedly a remedy in traumatic neurasthenia.—In the discussion which followed Mr. R. Pickard, Dr. J. Raglan Thomas, and Mr. Bell took part.—Mr. Roper replied.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Feb. 2nd, Mr. A. W. Cuff, the President, being in the chair.—Mr. R. J. Pye-Smith opened a discussion on Cases of Injury under the Workmen's Compensation Act, in Relation Specially to Diagnosis (with regard to justice of claim), Treatment (with regard to completeness of recovery), and Prognosis (with regard to resumption of work). He referred to statistics to show the large number of workpeople (over 7,000,000) affected by the Workmen's Compensation Act, the number of accidents at employment (nearly 350,000) occurring annually, and the fatalities (between 3000 and 4000). Probably less than 2 per cent. of all claims came before the county court judges for arbitration. In these cases he thought that the medical referees should be more frequently called on to act as assessors, as their presence exercised a healthy influence over the medical witnesses, and enabled the arbitrator better to appreciate such evidence and the physical condition of the injured man. The advantages of the Act, whereby the honest and industrious man received pay sufficient to keep his home together when disabled by accident, were largely counterbalanced in the case of the dishonest and lazy by such dangers as the temptation to make the most, instead of the least, of an injury, to exaggerate its effects, to abstain from proper remedial measures, to shirk work, to cheat his employer, to bring misery on his family, and to degrade his own moral nature. Mr. Pye-Smith insisted on the importance of a definite diagnosis and of making immediate written notes of negative as well as positive conditions. He discussed the persistence of pain as a cause for the prolongation of many cases resulting in honest differences of opinion between medical witnesses, the undue frequency of sepsis, the stiffness resulting from fractures and sprains, and the danger of inconsiderate suggestion. Prognosis was often particularly difficult, because the surgeon responsible for forming it usually had not control of the treatment; much also depended on the degree of honesty of the workman. Too many cases dragged on for an inordinately long period for lack of a definite idea of how long the case ought to last.—Mr. A. C. Turner pointed out that the Act was concerned with "loss of capacity for work from an accident," which was defined as "any mishap or untoward event which is not expected or designed." Whether the cause of injury was an accident or not was for the lawyers to decide, but the medical man must say if a given injury could be caused by a given accident. It was necessary to examine not only the injured part but the body generally. It was also very important to know exactly what work the man did, and to personally see such work done. The results of an accident had to be "natural and reasonable."—Dr. E. W. Adams pointed out that in cases of life assurance and private accidental injury the opinion of the medical referee was not often seriously challenged. But in cases of injury to workmen the medical man must be prepared to defend every statement of his report. He thought it would be a great help and advantage to have associated with the examiner an intelligent mechanic conversant with the particular process which the man would have to return to if certified fit. The prognosis, which was the most important factor from the insurance company's point of view, must include not merely an estimate of the time necessary for healing or recovery, but also the probable time required for the perfect functioning of the injured part.—Dr. F. J. Sadler showed a boy, aged 8 years, convalescent after Typhoid Fever complicated by "Meningitis," who had been treated by injections of killed typhoid bacilli.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Feb. 15th, Mr. W. Morley Willis, the President, being in the chair.—In opening a discussion on Syphilitic Throat and Skin Affections, Mr. J. Mackie confined his remarks chiefly to the diagnosis between syphilitic, tuberculous, and malignant disease of the throat and larynx. Chancre was rare in this region; on the other hand, it was a favourite site for secondary and tertiary manifestations of syphilis. The secondary stages did not last long and readily responded to treatment. In the tertiary stages gummata usually appeared on the posterior surface of the uvula, on the palate, and on the base of the epiglottis. The importance of the family medical attendant, who knew the history of the patient, was emphasised in the question of diagnosis. In doubtful cases iodide of potassium frequently cleared the diagnosis, and a careful examination of the chest and sputum would eliminate or prove the presence of tubercle.—Mr. J. P. W. Gray said that primary chancres were very rare in the region of the throat; they were accompanied by great enlargement of the cervical and submaxillary glands. After six weeks secondary manifestations appeared chiefly as (*a*) multiple, slightly infiltrated mucous patches on the fauces; or as (*b*) superficial ulceration of the mucous membrane accompanied with rather deeper infiltration. These symptoms were seen more commonly in women than in men, because the men, as a rule, were already under treatment and so often escaped. Five years after infective gummata might be found as tumours infiltrating the surrounding tissues. As these frequently arose behind the soft palate, they often escaped detection; moreover, they broke down with surprising swiftness, leaving a deep ragged ulcer, sometimes involving most of the uvula and one side of the pharynx. As this healed it led to serious deformities; in some cases the adhesions almost entirely shut off the post-nasal space from the pharynx. Syphilitic rhinitis in congenital disease was very amenable to treatment. The general treatment consisted in giving mercury and iodides, and in all cases ordering a mercurial lotion as well.—Dr. F. H. Jacob dealt chiefly with syphilitic skin lesions and the bacteriology of syphilis. The organism was best examined through a dark-ground condenser. Lupus was often difficult to diagnose from syphilis; the chief aids in the diagnosis were the pressure of a watch-glass which showed the apple-jelly granulations in lupus, the tuberculin test, the microscope, and the Wassermann reaction. The latter reaction had shown them that antisyphilitic treatment should be continued for three years; also that the best methods of treatment were: (1) "606," (2) the inunction method, (3) the injection method, (4) by means of suppositories, and (5) that oral treatment was the slowest and least satisfactory. In the tertiary stages

potassium iodide should be pushed to large doses—e.g., one drachm three times a day. Very often arsenic added to a mixture of iodide and mercury proved of great value.—Dr. C. H. Cattle, Dr. A. Stanley Green, and Dr. M. Parry-Jones continued the discussion.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held at the Medical Institute, Liverpool, on Feb. 17th, Dr. J. B. Hellier (Leeds), the President, being in the chair.—Dr. H. Briggs (Liverpool) showed several Obstetrical Mannikins, which he claimed rendered the teaching of operative midwifery both easier and more satisfactory.—The President showed an Intra-mural Myoma removed from a woman, aged 25 years, in her second pregnancy. The tumour had grown with great rapidity and showed some signs of degeneration. The patient had done well and had not miscarried.—Dr. J. E. Gemmell (Liverpool) showed specimens of: (*a*) An Ovarian Abscess Simulating a Fibroid, which had been noticed during a pregnancy some seven months before the operation. In the course of separating adhesions during the operation the abscess, which appeared to be intimately connected with the uterus and as large as a five months' pregnancy, was ruptured, and so panhysterectomy was performed. It was only on subsequent dissection that the tumour was found to be ovarian in origin. (*b*) A specimen showing Multiple Fibroids of the Uterus in one of which red degeneration had taken place. The operation (sub-total hysterectomy) was undertaken on account of severe hæmorrhage.—Dr. T. B. Grimsdale (Liverpool) described a case of Persistent Metrorrhagia in a woman, aged 35 years. The patient had been curetted on two occasions, but with only very temporary relief, so after consultation the uterus and one ovary in which there was a blood cyst were removed.—Dr. W. E. Fothergill (Manchester) read a paper dealing with the proper use of the word "endometritis" in teaching gynæcology. If this could be settled, definition in the use of other words like "metritis" and "ovaritis" would naturally follow. Endometritis certainly implied the inflammatory reaction of the tissues to irritation by septic, gonorrhœal, tuberculous, and other micro-organisms. The word was, in fact, the name of a pathological process. But it was constantly used as a name for various clinical states or diseases which were not caused by infective or other irritants. Amongst the conditions often called "endometritis" were pelvic hyperæmia, hyperplasia of the endometrium, sub-involution, the menorrhagia of puberty, the menorrhagia of the menopause, and even menorrhagia secondary to various general diseases. Dr. Fothergill considered, in the first place, that the teaching of gynæcology would gain in simplicity and accuracy if the use of words ending in "itis" were confined to cases in which there was clinical evidence, in the form of history, symptoms, or signs, that infection had played a part in the causation of the condition. Further, he thought it would be of advantage if words ending in "itis" were used only for pathological processes which occur in the course of infective disease, and were not used as if they were the names of diseases with independent and separate existence.

BATH CLINICAL SOCIETY.—A meeting of this society was held on Feb. 3rd, Mr. F. Lace, the President, being in the chair.—Dr. R. Waterhouse showed specimens of the Thymus Gland, weighing 24 grammes, removed from a child, aged 9 months, who died suddenly whilst being bathed, and the Thymus Gland of a child, aged 3 months, weighing 34 grammes, who died from asphyxia from pressure on the trachea, breathing having been embarrassed since birth; tracheotomy gave no relief.—Dr. G. J. King Martyn read a paper on the Use of the Calcium Salts. He gave a *résumé* of the known physiological effects of calcium on the tissues and blood and the evidence of the regulation of calcium metabolism by the thyroid gland. The intolerance of iodides in myxœdema was due possibly to the liberation of thyroid secretion on the cerebral circulation. He advanced the theory that sporadic goitre was due to compensatory hypertrophy of the thyroid gland to cope with added calcium metabolism induced by drinking certain limestone waters. The treatment of rheumatoid arthritis by thyroid extract was essentially the same as that by iodides. He pointed out that one of the benefits of cod-liver oil in rickets was due to its forming a soluble soap with calcium. As regards calcium increasing the coagulation of blood, clinical experience seemed to be contrary to recent experimental work. He instanced as morbid conditions in which he had found the administration of calcium beneficial: hæmophilia, epistaxis, chronic sneezing, chilblains, certain headaches, orthostatic albuminuria, and Henoch's purpura. He pointed out the relation of strontium to calcium and its success where the latter salt had failed. He ascribed the failure of calcium to produce benefit in some cases either to non-absorption or to its not being given over sufficiently prolonged periods. The question of calcium metabolism was of great interest with regard to the Bath waters. In these calcium was present only as the sulphate and carbonate and in small quantities. Hence it was probably not absorbed at all, or in such minute quantities as to do no harm. He had never seen thrombosis or other phenomenon which might be due to calcium absorption occur during the drinking of the waters. If, however, excretion of calcium in the body were desired, iodides could be taken with the mineral water. This was a valuable method of administration preventing iodism. He found the best preparations of calcium to be the lactate, the chloride, and the iodide, and mentioned a case of diplopism lasting 12 hours, and a case of "dualism" whilst taking the chloride which passed off without bad effects.—Dr. J. Lindsay read a paper entitled "Bilious Headaches," illustrating it by the case of a man, aged 51 years, in which these headaches recurred at regular intervals, commencing at the age of six.

THE NEW LONDON DERMATOLOGICAL SOCIETY.—A meeting of this society was held on Feb. 9th, at St. John's Hospital, Leicester-square, Dr. P. S. Abraham, the President, being in the chair.—Dr. G. Stopford Taylor (Liverpool) showed a case of Darier's Disease in a man, aged 33 years, with a general hypertrophy of the whole sebaceous system, which had commenced two and a half years ago.—The President showed a boy, aged 5 years, with Dermatitis Herpetiformis in the acute stage, in which staphylococci had been found in the bullæ.—Dr. G. Norman Meachen showed: (1) A child, 5 years of age, with Granuloma Annulare upon the right wrist of three months' duration; and (2) a case of Leukoplakia in a man, aged 83 years.—Mr. Dennis Vinrace showed a girl, aged 8 years, with Multiple Tuberculous Lesions after Varicella.—Dr. W. Knowsley Sibley gave a demonstration of the method of Hyperæmia in the Treatment of Skin Diseases, illustrated with cases.—Dr. W. Griffith showed: 1. A case of Severe Nodular Infiltration of the Thigh in a man aged 25 years. The case excited much interest, and several members expressed the opinion that the condition might be one of mycosis fungoides. 2. Erythema Multiforme in a man aged 24 years.—Dr. Morgan Dockrell showed a case of Syphilis in a young woman who had been treated by two intravenous injections of 0·4 gramme of "606," and Dr. Griffith demonstrated the apparatus used.

UNITED SERVICES MEDICAL SOCIETY.—A meeting of this society was held in the library of the Royal Army Medical College, Millbank, on Feb. 8th.—Fleet-Surgeon R. C. Munday, R.N., of H.M.S. *Hyacinth*, East Indies Station, read a paper on Different Types of Beri-beri Occurring in Naval Ships Cruising in the Persian Gulf during 1909-1910. He said that the number of men serving in the Gulf during 1909 was more than double that of any preceding year of modern times. The service is a very arduous one; no leave or exercise can be given to the men and the supply of fresh provisions is very limited and of poor quality. The number of Asiatics serving in the ships of the Persian Gulf numbered 182 in 1909 and 317 during 1910—a very considerable increase. In 1909 19 cases of beri-beri, with 7 deaths, appeared among Asiatics, whose staple diet was white, highly polished, over-milled, uncured rice; and as the result of substituting cured rice, increasing the nitrogenous part of the diet, and instituting other precautions, dietetic and otherwise, only two cases, and those doubtful ones, occurred in 1910. This was most satisfactory, but the extraordinary part was that although no Europeans were attacked in 1909 when the epidemic among the Asiatics occurred, in 1910 there were 17 cases of beri-beri among them, while, with the exceptions before stated, the Asiatics escaped. From the clinical evidence there could be no reasonable doubt that all these 17 cases should be classed as beri-beri. All classes were affected. Uncured, over-milled rice did not form part

of their diet; indeed, in many of the cases no rice was eaten, and Fleet-Surgeon Munday advanced the opinion that when beri-beri occurred in the Asiatic rice-eater the cause lay in the poverty of his rice, which had lost by over-milling certain necessary ingredients, but that when it occurred in the European *non-rice-eater* the cause lay not in the rice (which was not his staple food), but in a deficiency of some other article of food, which, or portions of which, were vital to the proper nutrition of his nervous system; that this lack might be brought about by inability to assimilate the necessary portions, even where present in the diet, through mal-digestion, caused by inferior quality of food, nervous depression due to climate, monotony of service, lack of exercise, &c.—The paper was discussed by Fleet-Surgeon W. E. Home and Staff-Surgeon O. Rees, and the debate was wound up by the President, Sir David Bruce, who expressed a strong hope that over-milled rice would be interdicted for the future. While expecting that the work of Fraser and Stanton and other observers would hold good, he could not help thinking that the explanation they offered was almost too simple. For his own part, he thought that probably some peculiar protein body had disappeared from the over-milled rice, though what it was no one could yet tell. This protein body might be absent from the diet of Europeans, as in the case of the European outbreak described in the paper.

HARVEIAN SOCIETY OF LONDON.—A meeting of this society was held on Feb. 9th, Mr. J. Ernest Lane, the President, being in the chair.—Mr. J. Jackson Clarke related the notes of two cases of Abscess of the Liver Complicating Appendicitis. Both patients were boys, one aged 8½ years and the other 4 years. In both the original lesion was an easily accessible, perforated appendix with abscess. The symptoms of liver implication were obscure, there being no downward increase of liver dulness and the upward increase occurring late; the chief symptom was fever of septic type not otherwise accounted for. In both cases exploration through the ninth intercostal space revealed the pus, so that part of the ninth rib was removed. The intrahepatic situation of the abscess was established at the operation. Infection of the pleura followed operation in one case in spite of the usual precautions. Both patients recovered completely.—Dr. Frederick J. McCann read a paper on the Surgical Treatment of Sterility in Women. He said that while sterility in women resulted from both gross and minute changes in the pelvic organs, surgical treatment was applicable only to the former. No major treatment should be undertaken until impotence in the male had been excluded. One-fourth of the cases of sterility were due to this cause. In the past attention had been given chiefly to malpositions of the uterus, and the ovaries had been neglected. Gonococcal and other infections led to adhesions in the tubes and ovaries and occlusion of the tubes. He described the operation of salpingostomy and said that a large incision was desirable; all adhesions must be separated, and the uterus suspended to avoid the formation of new ones. The tubes remained patent as had been proved in subsequent operations; no probe should, however, be passed. Suitable cases were those in which there was increased menstrual loss, with or without pain preceding the period, sacral backache, and possibly dyspareunia. Such cases showed on examination partial fixation of the uterus, though occasionally it was freely moveable, with tenderness if the tubes were thickened. There appeared to be no special liability to tubal pregnancy, although he was aware of one instance after this operation. For uterine displacements he advocated hysteropexy by an open operation rather than that of Alexander-Adams. Pregnancy often followed such operations. Pessaries should not be used. Curetting had very limited indications in the treatment of this condition, only cases of "chronic glandular hypertrophic endometritis" with the uterus normally placed, free loss, and normal tubes being suitable. Division of the cervix was often valuable for sterility associated with spasmodic dysmenorrhœa.—The paper was discussed by the President, Mr. A. C. Butler-Smythe, and Dr. R. Paramore.—Dr. McCann replied.

OXFORD MEDICAL SOCIETY.—A meeting of this society was held in the Radcliffe Infirmary on Feb. 10th, Mr. R. H. A. Whitelocke, the President, being in the chair.—Dr. A. L. Ormerod brought forward a scheme for the Voluntary Notification of Cases of Tuberculosis. He suggested that the practitioner in attendance and the patient should each sign the form of notification, and that such notification should give permission for the medical officer of health or his deputy to visit the house, examine contacts, and give general advice; that the practitioner should receive for each notification a fee of 2*s.* 6*d.*, and that each patient should only be notified once, such notification being made only after confirmation of the diagnosis by a bacteriological or physiological test. If the notification were signed by both the patient and the practitioner the responsibility of medical men became less. The reason for notification once only was obvious when it was considered that in the interests of public health each case must be kept under observation until death, and this in itself would prevent the hasty notification of doubtful cases.—Dr. W. D. Sturrock read a paper on Some Recent Work on Cancer. Having given a definition of an established cancer as a parasite rooted in its host, he outlined the broad divisions of work done on the subject. While work on metabolism was of great value, he had specially chosen for review the transplantation work done by the Cancer Research Fund workers and others. The main points brought out were that a successful transplantation needed a special reaction on the part of the connective tissue, which had to provide a stroma for the support of the growing graft, consequently the absence of such reaction made a graft powerless, and was an expression of immunity. Such immunity could be obtained experimentally and suggested the possibility of similar immunity being established towards secondary growths, which were somewhat analogous to transplanted growths. On the other hand, it appeared that too great a response of the connective tissue might strangle an established growth, and this again suggested a possible means of attack upon the primary growth itself by stimulation of the connective tissue.

# Reviews and Notices of Books.

*The Physiology of Reproduction.* By FRANCIS H. A. MARSHALL, M.A. Cantab., D.Sc. Edin., University Lecturer in Agricultural Physiology, Cambridge. With a preface by Professor E. A. SCHÄFER, Sc.D., LL.D., F.R.S., and contributions by WILLIAM CRAMER, Ph.D., D.Sc., and JAMES LOCHHEAD, M.A., M.D., B.Sc. Edin., F.R.C.S. Edin. With 154 illustrations. London, New York, Bombay, and Calcutta: Longmans, Green, and Co. Pp. 706. Price 21*s.* net.

IT is claimed for this work that for the first time the physiology of the organs of reproduction has been presented in a complete form, and that it furnishes a much needed introduction to eugenics. The book is addressed primarily to the trained biologist, though it is hoped that it may be of interest to medical men engaged in gynæcological practice, veterinarians, and breeders of animals. The physiology of generation in animals, more particularly in the higher forms and mammals—though invertebrates are not omitted—is specially discussed. Heredity, cytology, and variation are omitted intentionally, but a large part of the work deals with morphology. The breeding season in invertebrates and vertebrates is fully discussed, then the œstrous cycle in mammalia, and an account of the changes that occur at this season in the non-pregnant uterus, with details of histological and other changes in the ovary. Some of the figures are original, others are from Sellheim. The author is of opinion that there is no doubt regarding the essential similarity between the menstrual cycle in the primates and the œstrous cycle in the lower mammalia. A very interesting chapter is devoted to the ovary, oögenesis, growth of the follicles, ovulation, and corpora lutea. The account is very full, and confirms the views of Sobotta, that the luteal cells represent the epithelial cells of the undischarged Graafian follicles. Spermatogenesis and insemination are next dealt with, and mention is made of the process of artificial insemination, as first practised by Spallanzani. In discussing fertilisation the author is led to a study of the importance of Mendel's discovery. It forms

a basis for a theory whereby variability can be discussed in terms of the conjugating cells themselves. He states reasons for supposing that sex is a Mendelian phenomenon, but brings forward no good evidence for the existence of what has been called telegony. A full account is given of Loeb's work to elucidate the physico-chemical aspects of the phenomena of fertilisation.

There is a careful account of the accessory reproductive organs of the male. The biochemistry of the sexual organs is dealt with by Dr. Cramer, but really not much is definitely known of this subject, in mammals at least. There is an interesting chapter in which is collected what is known regarding the ovary and testes as organs with internal secretions, while the chapter on fœtal nutrition and the placenta is one of the fullest in the book. A special chapter on the changes in the maternal organism during pregnancy is contributed by Dr. J. Lochhead under the following heads: (1) The stimulus for the maternal changes during pregnancy; (2) changes in the metabolism of the mother; (3) changes in the maternal tissues during pregnancy. The innervation of the female generative organs, uterine contraction, parturition, and the puerperal state are next dealt with. Lactation, fertility, the factors that determine sex, the phases in the life of the individual, the duration of life, and the cause of death complete the wonderfully interesting story set forth by the author with perfect clearness, and with a supply of pictorial illustrations that adds greatly to the value of the work.

We feel sure that this book will be warmly welcomed by the biologist, as well as by the physiologist and those interested in the ever-growing subject of eugenics. The work is dedicated to Walter Heape, whose original work marks a period in the history of this engaging subject.

---

*A System of Syphilis*. In Six Volumes. Vol. V. Oxford Medical Publications. Edited by D'ARCY POWER, M.B. Oxon., F.R.C.S. Eng., and J. KEOGH MURPHY, M.C. Cantab., F.R.C.S. Eng. With an Introduction by Sir JONATHAN HUTCHINSON, F.R.S. London: Henry Frowde and Hodder and Stoughton. 1910. Pp. 356. Price £2 2*s*. per volume net, or £10 10*s*. net for six volumes.

The fifth volume of this very excellent "System" deals with the Affections of the Skin in Syphilis, by Dr. Phineas S. Abraham and Dr. Haldin D. Davis; Ocular Syphilis, by Mr. C. Devereux Marshall; Aural Syphilis, by Mr. C. Ernest West; and Syphilis in the Upper Air Passages, by Dr. StClair Thomson.

The first section, which deals with diseases of the skin, is excellently written, and contains a good account of the numerous skin eruptions that may be met with in this disease. Of necessity a good deal is repeated which has appeared in previous volumes, but without spoiling the completeness of the description this is inevitable, and it is, indeed, rather an advantage than a drawback, because it eliminates tedious and annoying cross references. The section contains some 30 illustrations, nearly all direct colour photographs, beautifully reproduced and of great merit.

In a short appendix to this section an account is given of the chemical nature and uses of the new remedy, dichlorhydrat-diamidoarsenobenzol, salvarsan, or "606," as it is commonly called. It is a great pity that these volumes have been published so soon after the discovery of this apparently specific drug for syphilis. It would have added greatly to the value of the work if the results of the administration of "606," as far as they have gone, could have been included, but unfortunately the book has been published just a few months too soon. Most of the reports which have so far appeared in our columns and elsewhere lead to the belief that the contentions put forward by Ehrlich with regard to this new remedy are by no means extravagant, and that it is possible that we may find in "606" a most valuable remedy for syphilis. It is already clear, however, that the drug must not be used without care and a proper selection of cases suitable for its administration, and the important question whether the results obtained are permanent or only temporary still remains to be solved.

The article on Ocular Syphilis, contributed by Mr. Devereux Marshall, forms an inclusive, and at the same time succinct, account of these important affections of the eye. Aural syphilis is one of the worst forms of this disease, at any rate when certain parts of the auditory tract are involved—for example, the labyrinth; and although the treatment of syphilis has made such vast strides during the last 50 years, yet the outlook in these distressing cases is still exceedingly hopeless. This has resulted from the extreme intractability of the conditions, the fact that the changes in the labyrinth are painless and insidious, and from their irremediable nature when once established. The very interesting subject of syphilitic affections of the nose, pharynx, and larynx is fully discussed by Dr. StClair Thomson, and there are some good illustrations accompanying this section.

On the whole, this volume is well up to the standard of the preceding ones and carries on the good work of the previous writers. The sixth volume was favourably reviewed in these columns a few weeks ago. The editors are to be congratulated on the uniform success that has attended the issue of each instalment of the book.

---

*Lehrbuch der Krankheiten des Herzens und der Blutgefässe* (*Handbook of Diseases of the Heart and Blood-vessels*). Von Dr. ERNST ROMBERG, o. Professor und Direktor der Medizinischen Klinik in Tübingen. Second edition. With 69 illustrations. Stuttgart: Ferdinand Enke. Pp. 588. Price 14 marks, bound.

RESEARCH, both clinical and experimental, in regard to the phenomena presented in disease of the heart and blood-vessels, has proceeded so rapidly during the last few years that the literature is enormous, and much useful information lies more or less hidden in monographs and in papers in periodical medical publications. A text-book affording a critical review of recent work and containing thorough descriptive accounts of the individual diseases and morbid conditions, while providing practical recommendations in regard to their treatment, should be of great value. Such a text-book is Professor Romberg's work. The appearance of a second edition is good evidence of the esteem in which it is held in Germany. In the preface to this edition Professor Romberg strongly urges that we should study the complex problems of the circulatory system in disease from as many aspects as possible, and he utters a strong note of warning against the tendency to over-estimate the value of any one mode of examination. As an example, while admitting the great help that has been afforded by the study of the venous pulse, he is of opinion that at the present time there is some danger of over-estimating the value of the conclusions drawn from it. It is this critical note, as well as its wide range, which gives this book its special value.

The introduction is devoted to general considerations, including anatomical and physiological details, and to the general methods of examining and recording the signs of cardio-vascular disease. The symptoms and physical signs of organic heart lesions are next categorically described in detail, including those due to the congestion of other organs. Chronic insufficiency of the heart muscle apart from valvular disease is fully described, and the various forms are clearly differentiated according to their etiology, each

form being noticed separately. The individual valvular lesions and the clinical manifestations of each are dealt with. Under the physical signs of aortic regurgitation Professor Romberg mentions the occurrence of Flint's murmur, but states that he has never yet observed it, a statement which seems remarkable, since this murmur is by no means extremely rare. He lays special stress on the occurrence of true aortic regurgitation without the presence of a diastolic murmur. Certain other general statements in regard to some of the left-sided lesions are not quite in accord with the generally accepted views in this country—e.g., mitral regurgitation is said to be the most difficult of all acquired valvular defects in diagnosis. Although it is explained that the chief difficulty consists in distinguishing between organic valvular defects and mechanical incompetence from muscular weakness, yet this is surely a lesser difficulty than the diagnosis of aortic stenosis. Again, it is stated that pure mitral stenosis is the rarest of all left-sided lesions; indeed, Professor Romberg states that he has seen only two cases. Admitting that regurgitation is a frequent accompaniment, clinically no inconsiderable portion of cases present physical signs of stenosis only, a fact which Professor Romberg afterwards admits. Congenital heart lesions are dismissed with but very brief notice, and this section is not worthy of the general character of the book. The treatment of chronic heart failure and of valvular defects is exhaustively considered, and constitutes the best feature of the work, while providing a clear account of German practice in this matter. The section is, moreover, admirably arranged, the various factors in treatment being dealt with separately and at considerable length.

Affections of the myocardium and of the endocardium are fully dealt with, and clear accounts are given of their clinical characters, diagnosis, and treatment. For the puncture of the pericardium to withdraw serous effusions, the method advised is to insert the trocar and cannula outside the left nipple line in the fifth or sixth interspace, at a spot where there is dulness, but where no impulse is felt or pericardial rub heard. Under the heading of diseases of the blood-vessels useful descriptions of arterio-sclerosis, aneurysm, thrombosis, embolism, and phlebitis are included. Lastly, the various neuroses of the heart and blood-vessels are considered. A few illustrations and extensive bibliographies at the end of each section add to the value of this useful book.

---

*Plant Anatomy.* By WILLIAM CHASE STEVENS. Second edition. London: J. & A. Churchill. 1910. Pp. 379. Price 10*s.* 6*d.* net.

THIS work deals with the anatomy principally of the higher plants from the standpoint of the development and functions of the tissues. It does not profess to be a work of reference comparable to De Bary's "Comparative Anatomy," but rather a book which the student can use when doing his practical work, the necessity of such work being emphasised by the inclusion of illustrative studies at the end of each chapter. We like the treatment of the subject-matter; the anatomy of plants, in our opinion, should be treated first from the physiological rather than the morphological point of view, and such treatment makes the subject of much greater interest to the student. Further, the work is not overloaded with details; this is an important feature, for sometimes text-books of an elementary nature give too many details, so that the tendency of the student is not to differentiate between fundamental and less important facts.

The volume under review starts with the consideration of the cell, and then passes on to the differentiation of the tissues, secondary increase in thickness, protection from injuries and loss of water, gaseous interchange, translocation of food-stuffs, storage of food, secretion, and excretion. Also there is a chapter on reproduction, which includes the development of microspores and macrospores, together with a short account of Mendel's laws and some features arising therefrom, a subject which seems to have been dragged in without reason. The latter portion of the book deals with micro-technique, and the two final chapters are concerned with the micro-chemistry of alkaloids, glucosides, carbohydrates, colouring matters, and other plant products, and with the detection of adulterations in foods and drugs respectively. It is thus seen that the range of the book is pretty wide.

We think that the continuity of protoplasm in sieve-tubes and other elements should have been dealt with in the more descriptive part of the book rather than in the chapter on the micro-chemistry of plant products. As it stands, this important phenomenon may be overlooked. The same criticism also applies to callus, which might have received more attention. In a few cases statements might have been qualified; thus, on p. 36 it is written that "the walls of both sieve-tubes and companion cells remain cellulose." The qualification appears desirable, since in the sunflower, a type very commonly used in this country, lignification of the sieve-tubes may take place. There are 152 illustrations, many of which are original and the majority very good.

We consider the book on the whole distinctly good. The clearness of statement, the sufficiency of figures, and the practical directions make it a work that can be safely recommended, not only to the student working under the direction of a teacher, but also to the amateur who has no such advantage.

---

*Manual of Human Embryology.* Edited by FRANZ KEIBEL (Freiburg-i.-Br.) and FRANKLIN MALL (Baltimore, U.S.A.). In two volumes. Vol. I. With 423 illustrations. London and Philadelphia: J. B. Lippincott Company. 1910. Pp. 548. Price 30*s.* net.

THIS is the work of a number of German and American embryologists who have collaborated in its production, and the work itself appears simultaneously in Germany and America. The chapters originally written in German have been translated by Professor McMurrich, while the English chapters have been translated for the German edition by one of the editors—Dr. Franz Keibel, who is also responsible for a short historical introduction. Von Baer he rightly regards as the real founder of comparative embryology; indeed, his epoch-marking treatise was considered by so high an authority as Kölliker to be "the best that embryological literature of all times and all peoples has to show." Dr. Keibel also discourses clearly, suggestively, and comprehensively through 90 pages on the germ cell, fertilisation, segmentation, young human ova and embryos, the formation of the germ layers, the gastrulation problem, and gives a summary of the development of the human embryo and the differentiation of its external form.

The human ovum retains its transparency in all stages of development, but it possesses no micropyle. The author found human spermia still motile on the third day in the testes of an executed criminal, the organs having been placed unopened in picro-sublimate; but gynæcologists have observed motion after much longer periods, while in bats the spermia may remain active for months in the female genitalia. "Nothing is known concerning the fertilisation of the human ovum," and "the segmentation stages of the human ovum have not yet been observed." Nor has the formation of the germ layers been observed in the human ovum. In the description of very young ova the author

makes use of the ovum described by Teacher and Bryce, that described by H. Peters in 1899, and the more or less perfectly described human ova by other observers. The summary of development of the human embryo and the differentiation of its external form follows pretty closely the lines of His, and some of the excellent illustrations are taken from Retzius and from Keibel's own faithful representations of embryos at different stages.

To Grosser of Prague is entrusted the development of the egg membranes and the placenta, and also the subject of menstruation, which together occupy another 90 pages, comparative placentation being omitted. It would appear that the mucous membrane of the corpus uteri is never in a completely resting condition in a fertile female. Growth and degeneration alternate regularly and form together a menstrual cycle of normally 28 days, which cycle may be divided into certain more or less clearly marked periods or phases, which are carefully described, and the morphological changes figured and illustrated by several faithful woodcuts from Hitschmann and Adler. Professor Mall contributes an excellent chapter on the Determination of the Age of the Human Embryo, and also one on the Pathology of the Human Ovum. Both chapters are well illustrated by woodcuts. The latter half of the work is devoted to the Development of the Integument and its Appendages, by F. Pinkus; the Skeleton and the Connective Tissues, by C. R. Bardeen; the Muscular System, by W. H. Lewis; and the Cœlom and Diaphragm, by Professor Mall himself.

So far as it goes, this book is the most complete treatise on human embryology which we possess in English and will be welcomed by all workers in this subject. The bibliography is very full. Many standard works are laid under contribution for illustrations, the whole number, with numerous original figures, making a total of 423. Many of them are rendered more helpful by being coloured. The book, especially those chapters dealing with the integument and connective and muscular tissues, will also prove useful to the histologist, quite apart from the very elaborate treatment of the morphogenesis of the skeletal system, which will appeal to anatomists.

We commend this treatise cordially to the attention both of gynæcologists and of embryologists as a storehouse of information, well arranged, and full of data drawn both from animal and human embryology.

---

*Electrotherapeutics and Roentgen Rays.* By MIHRAN KRIKOR KASSABIAN, M.D., Director of the Roentgen Ray Laboratory of Philadelphia General Hospital, &c. Second edition. Revised and enlarged. London and Philadelphia: The J. B. Lippincott Company. 1910. Pp. 540. Price 15*s.* net.

A MELANCHOLY interest attaches to the appearance of this work in this country in that it synchronises with the announcement of the death of the author from the effects of chronic X ray dermatitis. He was a hard and earnest worker, and, in fact, was attending to his duties within a day or two of his end. It was our pleasure to review the first edition of his book some three years ago, and the changes and the additions in the issue before us are a great testimony to the advances made in radiology during recent years. It is not necessary to review the whole book in detail; we notice among the new material chapters dealing with instantaneous radiography, tele-radiography, chromo-stereoradiography, and plastic radiography. These are all very complete and may be considered an accurate guide to the practice of the novel applications of X ray technique.

But we wish Dr. Kassabian, with his large experience, had given us more of his own opinions and not taken up so much of his book in quoting the opinions and experiences of others, although no doubt the preparation of so much material entailed a great deal of work and much reading.

Throughout the book numerous excellent illustrations have been added to demonstrate more clearly the various modifications of practical X ray work.

---

*A Practical Guide to the Newer Remedies.* By J. M. FORTESCUE-BRICKDALE, M.A., M.D. Oxon., Assistant Physician to the Bristol Royal Infirmary; Lecturer in Pharmacology in the University of Oxford; and Clinical Lecturer in the University of Bristol. Bristol: John Wright and Sons, Limited; London: Simpkin, Marshall, Hamilton, Kent, and Co., Limited. 1910. Pp. 273. Price 5*s.* net.

THE author is careful to point out in his preface that this book does not concern itself with patent medicines or secret remedies, nor does it deal with therapeutic methods as such. A successful attempt has been made to pass in review the newer drugs (mainly the products of synthetic chemistry) the composition and the pharmacology of which have been more or less accurately ascertained. In order to give a practical value to the work the various drugs described have been criticised and compared, and the experimental and clinical evidence for and against the usefulness of each has been carefully weighed, whilst in all cases directions are given as to dosage and the usual mode of administration. Much valuable information is contained in this work, and the complete manner in which the investigations have been made gives confidence in the opinion expressed by Dr. Fortescue-Brickdale.

The paragraphs on arsenic and its compounds will be found of interest. The cacodylates and arylarsonates are duly described, especial attention being drawn to atoxyl. The conclusion is arrived at that in syphilis injections of atoxyl cannot take the place of the classical treatment by mercury, although in many cases a temporary improvement occurs. One of the best chapters in the book is that on hypnotic drugs. A large number of synthetic hypnotics are now on the market, and, speaking generally, they have been found satisfactory clinically. It is pointed out, however, that they vary considerably, both in their chemical composition and in their physiological effect, so that instead of increasing the dose of a mild hypnotic if it fails to produce sleep the physician may employ another of greater strength, and thus avoid, perhaps, unpleasant after-effects. For purposes of description a practical method of grouping is adopted. The first division is headed "Dangerous Hypnotics"; amongst these are included tetronal, isopral, chloralose, and chloralurethane. Division II. contains those hypnotics "having no special advantages"; amongst these are mentioned trigemin and propion. In Division III. the "mild hypnotics" are discussed, such as urethane, hedonal, and chloralamide. We agree with the opinion expressed that the last named is one of the safest hypnotics, and it is especially indicated when there is cardiac weakness. Division IV. contains the "medium hypnotics," such as paraldehyde and sulphonal. Division V. contains the "powerful hypnotics," such as trional and veronal. Other chapters worthy of study are those devoted to anæsthetics and to antipyretics.

Dr. Fortescue-Brickdale has supplied a useful guide to the use of those drugs which have been more recently introduced.

---

## LIBRARY TABLE.

*Diseases of the Skin, including Radiotherapy and Radiumtherapy.* By ERNEST GAUCHER, Physician to the St. Louis Hospital, Paris. Translated by C. F. MARSHALL, M.D. Vict., F.R.C.S. Eng. London: John Murray. 1910. Pp. 460. Price 15*s.* net.—The expectations aroused by the announcement of a volume on skin diseases by Professor Gaucher have

not been disappointed by a perusal of the book. Special articles have been written for the volume, adding greatly to its usefulness and interest. Thus, Wickham, Degrais, and Domenici describe the recent developments of radiumtherapy; Monier-Vinard writes on sporotrichosis, Rubens-Duval on blastomycosis, and Domenici on mycosis fungoides. For the English reader much of the interest of a book on dermatology, written by one of the physicians of the St. Louis Hospital, lies in the novel methods of description and treatment. It appears strange, for example, that at St. Louis psoriasis should be treated chiefly with arsenic, and that no mention is made of the excellent results obtained, especially in acute cases, with salicylic acid. In all English text-books we should find chrysarobin described as the best local remedy. Professor Gaucher mentions it among a list of other drugs, and pauses only to consider its disadvantages. In the descriptions of comedones, acne, and seborrhœa, the conclusions of Dr. Sabouraud are but lightly referred to; perhaps a wise step in a book intended chiefly for students. The practice of radiotherapy in dermatology has been carried probably to a higher degree in France than in any other country, and when this is remembered Professor Gaucher's remarks on p. 40 will be noted with interest and some surprise. In his experience there is a form of skin disease which is peculiar to operators, who, he says, suffer from a radioneuritis due to an ascending neuritis which is manifested by thin glossy skin, telangiectases, ulcerations and fissures, and papillomas which may become epitheliomatous. This condition is caused by repeated small doses of the rays, and Professor Gaucher says he has seen three cases. In this country such conditions have been so frequently seen both in operators and in patients who have had many short exposures to the Roentgen rays that the only conclusion to be drawn from Professor Gaucher's extremely limited experience is that French operators must have employed proper precautions for their safety in advance of other nations. The illustrations have been taken mostly from models in the St. Louis Hospital Museum and from Professor Gaucher's private collection, and it is matter for regret that the process of reproduction has not done justice to the models; few give a clear representation or clinical picture of the disease. This drawback to an excellent text-book should be remedied in a future edition. The book is written with an ease and fluency which render it most attractive reading. The descriptions are vivid, brief yet complete, and stimulate thought. The volume will meet the needs of the advanced student who desires something between the small handbooks and the large volumes such as those of Dr. Radcliffe Crocker.

*West African Hygiene, with Recent Observations on Yellow Fever and West African Fevers.* By EDWARD F. GRUNE, M.R.C.S.—This little pamphlet, which does not appear to be on sale, is stated by its author to have been written with a view "to disseminate the most recent of opinions of those at work on the spot where the diseases are prevalent." Although it has professedly been prepared for the benefit of members of the medical profession as well as for ship captains and others who may be called upon unexpectedly to deal with tropical fevers when skilled advice or assistance is not available, it appears to us that the work is more suited for the latter class than for the former. Perusal of the pamphlet, however, may stimulate some readers to seek further information in the recognised text-books on the subject. Much of the advice given may be regarded as sound and sensible, but we fear some may raise objection to the statement that "in tropical countries it is most important constantly to smoke cigars, and ladies should not hesitate to smoke cigarettes," to keep the mosquito at bay. We were under the impression that there was now a general agreement in the scientific world to designate the transmitter of yellow fever as the "Stegomyia calopus," but in this work the author calls it sometimes the "Culex fasciolata"; at other times the "Stegomaier fasciolata" or the "Stegomayer mosquito." Whether the work is intended for medical or non-medical readers care should be taken that the scientific terms are given correctly.

*Saunders' Question-Compends. No. 1: Essentials of Physiology.* Prepared especially for Students of Medicine. By SIDNEY P. BUDGETT, M.D., Washington. Third edition. Revised by HAVEN EMERSON, A.M., M.D., Demonstrator of Physiology in Columbia University, New York. Arranged with Questions following each Chapter. Illustrated (Figs. 27). London and Philadelphia: W. B. Saunders Company. 1909. Pp. 250. Price 4*s.* net.—These abbreviated lecture notes are intended for students to read with a text-book and not as a substitute for a larger work, which "Compends" often pretend to be, but are not. Histology and reproduction are practically omitted, while the notes on the senses, except the eye, are very condensed. The diagrams of tracts and connexions in the central nervous system are useful. The text runs on pleasantly, and so far as it goes it gives a straightforward account of the subjects with which it deals, but the information given would not meet the requirements of the higher examinations in this country. The book is, however, suitable for a rapid *coup d'œil* to refresh the memory. Names of famous experiments and their authors and dates of great discoveries are strikingly absent, as are descriptions of methods. The words "kymograph" and "sphygmograph" do not find a place in the index, which is copious. Globulicidal is given correctly in the index, but as "globucidal" in the text. On p. 48 it would be more correct to read "ventricles" than "ventricle." The weakest part of the work is that on digestion. Lipase is not mentioned as such, and the text is still in the "amphopeptone" stage. Enterokinase, erepsin, gastrin, secretin, and hormones are conspicuous by their absence. A suggestive feature is the list of questions—"Why does serum remain liquid at 0° C."? Should distilled water not be injected into the blood-vessels? Is the respiratory quotient of a herbivorous animal modified by starvation? Many of the questions are ingenious, and framed to test the student's knowledge of the text.

*Self and the Other.* By VICTORIA CROSS. London: T. Werner Laurie. Pp. 303. Price 6*s.*—The book can be recommended only to those who like sensationalism, wild improbabilities, and medical absurdities. The hero is attacked by "congestion of the lungs" while living in a Civil Service college, and is devotedly nursed by a young Hindoo lady who is studying medicine at a neighbouring college. She looks after him for a fortnight and feeds him on curry. Naturally they fall in love with each other; they go to Constantinople together; the plague breaks out and the Hindoo lady does wonders in nursing the sick. Finally, she is attacked by what we suppose Miss Cross means to be plague, but her description of the disease reads like an account of the symptoms of cholera. She dies, and over her body the hero cuts his throat with a razor, but while "a flood of hot blood streamed down and over her breast and neck" he does not die, although in addition we are informed on p. 290 that he had plague and "brain fever." A note, presumably by the publisher, on the loose cover of this novel informs us that "It is impossible to give a description of this book—the greatest thing Victoria Cross has done," so we shall not make further attempt.

## JOURNALS AND MAGAZINES.

*Annals of Tropical Medicine and Parasitology.* Vol. IV., No. 3. Dec. 20th, 1910. Liverpool: University Press. London: Archibald Constable & Co. Illustrated. Pp. 116. Price 7*s.* 6*d.* net.—The last number of the *Annals of Tropical Medicine and*

*Parasitology* contains the following contributions: (1) Some Enumerative Studies on Malarial Fever, by Major Ronald Ross and David Thomson; (2) A case of Blackwater Fever followed by a Peculiar Relapse without Hæmoglobinuria or Detectible Plasmodia, by the same authors and G. C. E. Simpson; (3) On Hæmoglobin Metabolism in Malarial Fever, by G. C. E. Simpson; (4) Some Observations on a case of Sleeping Sickness, Coagulation Time of Blood, Albumoses, Choline, Cerebral Sections, by Vishnu T. Korke; (5) Some Observations on Malaria in Relation to Splenic Enlargement and the Treatment of the Crescentic Stage, by N. F. Surveyor; (6) On the Peculiar Morphology of a Trypanosome from a Case of Sleeping Sickness and the Possibility of its being a New Species, by J. W. W. Stephens and H. B. Fantham; (7) on the Pathogenicity of a Trypanosome (T. rhodesiense, Stephens and Fantham) from a Case of Sleeping Sickness contracted in Rhodesia, by Warrington Yorke; (8) on Three New Species of the Genus Glossina, together with a description of the Hitherto Unknown Male of Glossina grossa (Bigot), by Robert Newstead; and (9) Descriptions of a New Genus and Three New Species of Anopheline Mosquitoes, by Robert Newstead and H. F. Carter. Of these, Nos. 1, 3, and 6 are reprinted from the Proceedings of the Royal Society, but are not the papers referred to in an annotation in THE LANCET of Jan. 21st, 1911, p. 182. 1. In this paper some observations upon the number of parasites present in relation to the various "pathological and therapeutical reactions" are recorded. The details of 33 cases are given at the end of the paper. The authors have come to the conclusion that there is a very decided correlation between the number of asexual plasmodia found in the blood and the fever; that as a rule no fever exists unless the asexual forms exceed some hundreds per cubic millimetre; that the asexual forms do not always disappear between relapses; that considerable and continued doses of quinine reduce the asexual forms by 50 to 80 per cent.; that it is probable that the sexual forms require 8 to 10 days for development; that quinine does not affect the sexual forms when once produced, but "ultimately reduces their numbers by destroying the generating cells"; and the hæmoglobin falls markedly with fever, but rises rapidly with convalescence. 3. Dr. Simpson comes to the interesting conclusion that "the main excretory channel for the pigment portion of the blood is the alimentary tract," and that urinary urobilin represents only a small overflow from this source. He considers that the elimination of urobilin is chiefly in the fæces. His method of extracting the urobilin from the fæces was by repeated shaking with large amounts of water acidulated with dilute sulphuric acid, and exposing the filtrates to daylight for some time. There appear to be so many sources of error possible here that we are inclined to agree with Dr. Simpson when he says "the figures obtained may later require revision," although his observations seem to show that his general conclusion is correct. 5. Dr. Surveyor records a series of observations made during 1908–10 when the city of Bombay was highly infected with malaria. Several cases were in a moribund state, and "the blood was found to contain typical rings and crescents in large numbers." It was, however, noticed that in spite of severe infection many cases had no fever, and splenic enlargement was absent. His observations with regard to temperature do not appear to agree with those of Major Ross and Dr. Thomson in (1), but it is to be noted that a number of his cases were of the malignant tertian type. His records of the results of treatment with picric acid and with quinine, of cases in which crescents were present, showed greatly in favour of picric acid. 6. Dr. Stephens and Dr. Fantham describe a trypanosome similar in its morphological characters to T. gambiense, except that among the "stout or stumpy" forms some have the nucleus at the posterior or non-flagellar end. This character seems fairly constant. A striking fact with regard to this strain of trypanosomes is that there is considerable evidence against the possibility of the patient from which it was obtained having been infected through Glossina palpalis. Dr. Warrington Yorke (7) shows that this strain is more virulent to rats, monkeys, mice, guinea-pigs, rabbits, and goats than T. gambiense. It seems that the view that we have in T. rhodesiense (as Dr. Stephens and Dr. Fantham propose to name this form) a new species is well founded.

*The Archives of Internal Medicine.* Vol. VI., No. 5. Nov. 15th, 1910. Chicago: American Medical Association. Subscription price, $4.00 per annum; single copies, 50 cents. —The contents of this number are: 1. The Use of Pure Lipoids and Alcoholic Extracts with Active and Inactive Serum in the Complement Fixation Tests for Syphilis, by Thomas MacRae, A. B. Eisenberg, and Homer F. Swift. This paper includes a comparative study of the effects of using ethereal extracts and alcoholic extracts as antigens. It is stated that the Noguchi method, using active serum, gives the most sensitive reaction in syphilis, the Wassermann and the Noguchi inactive methods standing in the order named. 2. The Wassermann Reaction in the Pathology, Diagnosis, and Treatment of Syphilis, by Richard M. Pearce. A valuable summary is given of the Wassermann reaction and of its practical uses, together with an extensive bibliography. 3. Peculiar Elongated and Sickle-shaped Red Blood Corpuscles in a case of Severe Anæmia, by James B. Herrick. Details are given of a case with very unusual forms of erythrocytes, which are well shown in a plate appended to the paper. 4. The Elimination of Bacteria from the Blood through the Wall of the Intestine, by Alfred F. Hess. Dr. Hess records experiments which demonstrate that bacteria are excreted from the blood, not only by way of the liver through the bile and by the kidneys through the urine, but also to a less extent directly through the intestinal wall. The organism used in these experiments was bacillus prodigiosus. 5. Experimental Lung Anthracosis, by Lewis Sayre Mace. Some experiments are described with talc injected into the peritoneal cavity of guinea-pigs, to test the correctness of the intestinal origin of anthracosis. 6. The Induction of Pancreatic Activity by the Removal of the Adrenals, by J. E. Sweet and R. Pemberton. 7. A Case of Fatal Sodium Chloride Poisoning, by Harlow Brooks. 8. An Experimental Study of the Resistance to Compression of the Arterial Wall, by Theodore C. Janeway and Edwards A. Park. These authors find that the arterial wall offers definite resistance to compression; that in infancy and childhood, and in adults with normal arteries and a normal range of blood pressure, the resistance of the arterial wall is practically negligible. Atheroma is without appreciable effect on the compressibility, while calcification of the arterial wall increases only moderately its resistance to compression. They suggest that the only factor capable of introducing an error of marked importance into the clinical estimation of blood pressure is the state of contraction of its walls, and they insist that the point of return of the pulse after obliteration should always be the criterion of systolic blood pressure. 9. Cutaneous Tests with Corn Extracts in Pellagrins. The results are given of some experiments to determine whether patients suffering from pellagra showed any hypersensitiveness to extracts from samples of good or spoiled corn (maize). These were negative in all cases.

*Jahreskurse für Ärztliche Fortbildung.* (*Annual Post-graduate Review.*) Munich: Lehmann. Price 16 marks per annum.—The January part is occupied with general physiology and pathology. Professor Johannes Müller deals in the most interesting manner with the intricate problems of the activity of the heart. In the first place the cardiac

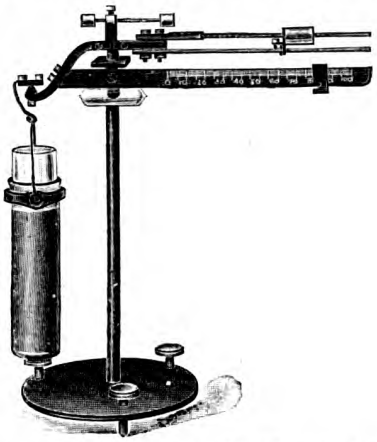
automatism is established on the grounds of numerous experiments. These for the hearts of warm-blooded animals have been made possible by Martin's discovery, that such a heart will go on beating like that of a reptile if only the circulation in the coronary vessels be kept up by injecting an artificial serum into the root of the aorta. Whether any internal glandular secretion is necessary for the maintenance of the cardiac activity is held to be an open question. The region of the roots of the great veins is regarded as the origin of the automatic impulse. The refractory phase, the "all or nothing" law of response to stimuli, and the nervous or muscular origin of the automatism, are carefully discussed. The influence of physical and chemical conditions on the activity of the heart is described under the following heads—viz., temperature variations, oxygen, inorganic salts, and grape sugar. Professor Lubarsch follows with an article on pathology, which is for the most part concerned with the heart. The anatomy, development, and structure of the auriculo-ventricular bundle are shortly described as an introduction to the discussion of the rôle of this structure in relation to disease. In many conditions—e.g., rheumatic carditis and fatty degeneration—the bundle is specially affected by the pathological process. It is regarded as playing a most important part in the conduction of the activity impulse from one part of the heart to another, bridging over, as it does, the fibrous septa which intervene between the auricles and ventricles. This view of its function is of particular interest in connexion with the facts of its relation to cases of the Adams-Stokes syndrome, which is due to the different parts of the heart not acting in harmony. Many cases of sudden heart failure are regarded as the result of disease of this auriculo-ventricular bundle. A few pages are given to the complex and bewildering facts concerning what are called the "chromophile tissues." These, named from their reaction to chromium salts, include the medullary part of the suprarenals, the carotid "gland," and parts of the sympathetic nervous system. Calcium metabolism is in some very close way connected with these structures. Animals deprived of their suprarenals develop a condition like that of rickets or osteomalacia. Further, the excessive administration of adrenal extract causes diabetes in animals. It is considered that there exists a marked antagonism between the functions of the "chromophile tissues" and that of the pancreas. The relation of the pancreas with diabetes is reviewed, and the theory which relates it to the islands of Langerhans is upheld as the result of recent research, especially that of Wechselbaum, who has collected 183 cases and subjected them to careful microscopical examination. The value of Wassermann's reaction in pathology is referred to, as it serves to clear up the nature of many a doubtful post-mortem finding. The reaction is given as well in the dead blood as in the living.

# New Inventions.

## SPECIFIC GRAVITY APPARATUS.

A DESCRIPTION of a new instrument for the determination of the specific gravities of different liquids will, I believe, be appreciated by the members of the medical profession. With the existing instruments (more especially represented by the urinometer) many difficulties and errors tend to make what should be a very simple operation one which is continually doubtful as to obtaining a perfect result. First and foremost is, of course, the expansion of the glass bulb of the instrument by an increase in the temperature. To such an extent does this occur that the variation from a hot to a cold day will produce a very appreciable difference in the result. Again, the annoyance caused by the instrument "climbing the tube" is very real. I refer to the tendency of the urinometer to be attracted to the side of the vessel containing the urine, and to be pulled up the side by capillary attraction.

The difficulty, again, of reading the scale from the under surface of the liquid when the urine is turbid is one which is both most annoying and frequent. Again, in examining candidates for life assurance every medical man must at some time or other have appreciated the difficulty of obtaining sufficient urine for the purpose. The assurance companies lay a special stress on the point that the urine should be passed in the presence of the medical examiner, but in very many cases (owing mostly to nervousness on the part of the candidate) the quantity of urine at the disposal of the examiner is entirely inadequate for the purpose. It is believed that the instrument illustrated will meet all these objections. As will be noticed, it partakes of the form of a small steelyard, fitted with a very sensitive spirit



level. The tube containing the liquid to be examined is suspended from the short arm of the instrument and the weights on the long arm are moved to the right or left, as may be necessary, until the bubble of the spirit level occupies a central position. The tube containing the liquid holds approximately 150 drops, and, of course, may be used for urine, milk, or any other liquid. The upper scale is graduated to divisions of 100, and the lower scale to tens and units, and in addition a small vernier on the rider enables the reading to be carried to a further figure, thus allowing the calculation to be made to four decimal places—e.g., 1·0607. The instrument, as at present made, is constructed with tempered steel knife edges, though, of course, agate bearings may if preferred be substituted. A range may be obtained of from 0·0001 to 2 with the single instrument, and this, I believe, will be admitted to be a large scope for an instrument which measures only 6 inches in length.

Such a method, exact in its results, easy to calculate, and quick in determination, I venture to hope will prove of value to the medical profession generally. Any inquiries regarding the instrument may be made to Mr. W. Martindale, 10, New Cavendish-street, where the instrument may be seen.

Fleet, Hants. C. BUTLER SAVORY, M.D., M.Ch.Edin.

## A TUBULAR MOUTH PROP.

THE importance of a good air-way and the advantages generally of the use of a mouth prop in certain cases have been frequently pointed out by Dr. F. W. Hewitt and others.

The advantages of a tubular prop over a solid were first pointed out by Dr. W. McCardie. For the last three years I have been using a tubular mouth prop which has given me much satisfaction in cases in which the air-way required improving. It is shown in the illustration, and is made for me by Messrs. G. Barth and Co., of Poland-street, W. One end is much smaller than the other, and if the mouth simply requires keeping open or the lower jaw to be pushed forward this smaller end is inserted. This is easily done, as the mouth has to be opened to a small extent only, and even if the patient is not fully under the use of a gag is hardly ever required, as is more often necessary if the mouth has to be opened wider. In edentulous cases the tendency is to blow out a mouth

prop, not to suck it in; therefore the larger end is inserted in these cases, and it remains between the gums and lips, and is not blown out. If an "artificial air-way" is required to conduct the air behind the tongue, the advantages of which in certain cases have been pointed out by Dr. Hewitt, a perfectly efficient one can be made in a moment by pulling a stout piece of indiarubber tubing over the smaller end as shown by the dotted lines in the illustration. There is an advantage in being able to alter the length of the tubing to suit the depth of the mouth, and I carry three lengths with me. The tubing must be of a fairly rigid kind, or it may be pressed flat against the hard palate. Though the mouth is not unduly opened the air-way is of sufficient size. There is a hole in the larger end to tie it to a wooden wedge or other prop outside the mouth. I have found a tubular prop useful even in the case of small children with much blocked post-nasal cavities, and Messrs. Barth and Co. make these props in three sizes. Amongst other uses of a tubular mouth prop, it is occasionally an advantage to pass the metal mouth tube of a Junker's apparatus through it and allow air to enter the mouth, and if the Junker mouth-tube is forgotten or perhaps dirtied the indiarubber tube can safely be passed between the teeth through the tubular prop.

H. M. PAGE, F.R.C.S. Eng.,
South Kensington, S.W. Anæsthetist to Guy's Hospital, &c.

## A NEW NASAL BATH.

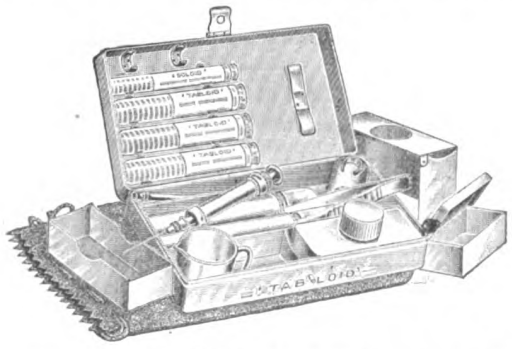
THERE is much divergence of opinion as to the best means of cleansing the nasal cavities, some employing douches, some sprays, and some syringes. Each of these methods has its advantages, but for children and others who are none too careful an apparatus brought to my notice by the Nazene Company of Great Marlborough-street, London, W., and designated by them the nasal bath, seems to be well suited.

It is exceedingly simple in construction, is sterilisable, and is very compact. It can be carried in the pocket quite easily. It is not liable to be broken, nor can it do any damage to the delicate nasal mucous membrane, as sometimes occurs with glass and rubber syringes. Its advantages over the latter are that it will never wear out and is much more cleanly. Patients like this bath, and find it very convenient and effectual.

WILLIAM IBBOTSON, M.R.C.S. Eng., L.R.C.P. Lond.
The London Throat Hospital, Great Portland-street, W.

## A "TABLOID" QUININE INJECTION POCKET-CASE.

THE administration of quinine by hypodermic or intramuscular injection instead of by the mouth is a therapeutic measure which of late years has been growing in favour, and in certain conditions it has advantages over the older



and more usual method. Recognising this, Messrs. Burroughs, Wellcome and Co. have sent for our inspection an outfit which comprises everything necessary for making such injections. The "Tabloid" quinine injection pocket-case is an elegant, compact, and complete outfit. Within a nickel-plated metal case, so small as to be easily slipped into the pocket, are contained a 20-minim all-metal syringe, with needles, a supply of "Tabloid" hypodermic quinine bihydrochloride, a pair of forceps, "Soloid" corrosive sublimate for the preparation of the patient's skin, and all the apparatus—including a sterilising cup and tray, a spirit-lamp, and a match-box—required for the sterilisation of the syringe and the quinine solutions. With the aid of this outfit the practitioner can make sure in practically any circumstances that his injections of quinine are given under aseptic conditions, and the pocket-case should prove useful in all countries where malarial affections are prevalent.

## REPORT ON THE WORK OF THE CENTRAL MIDWIVES BOARD FOR THE YEAR ENDED MARCH 31ST, 1910.

DURING the year under review the Board has met 16 times, including four special meetings for the investigation of cases where a local supervising authority had reported a midwife for malpractice, negligence, or misconduct. Sir Francis Champneys was re-elected chairman, but there have been some changes in the constitution of the Board, for Sir George Fordham has resigned the post of honorary treasurer, Mr. J. Ward Cousins has been succeeded in the representation of the Royal College of Surgeons of England by Mr. C. H. Golding-Bird, and Dr. G. E. Herman represents the Incorporated Midwives Institute in the place of Dr. Stanley Atkinson, deceased. The total number of trained midwives on the roll is 17,790, as against 11,419 untrained, but as a large percentage of trained women obtained their certificates without any intention of ever practising, and many others have ceased to practise or are practising in the colonies or in foreign countries, the untrained practising midwives are largely in excess of the trained. The number of penal cases—namely, 53—when compared with the 92 cases of last year, apparently shows a large diminution in the charges of negligence and misconduct, but this diminution is mainly due to the fact that the penal sittings usually held in March were held in April this year, and do not come under review in this report. The penal procedure of the Board as laid down in Rule D has been under consideration. The rule provides that the "secretary or other person appointed by the Board" shall conduct the case against a midwife charged before the Board, after a *primâ-facie* case has been established against her by the local supervising authority. In one or two cases the local supervising authority has claimed to have the conduct of the case, and as this would introduce confusion into the proceedings the Board has passed a resolution disallowing it, and refusing a hearing to the authorities, except when charges having been brought against its officers an answer is to be reasonably expected. The number of cases of ophthalmia neonatorum coming to the notice of the Board in the course of its penal administration has made it apparent that strong efforts are necessary to combat the ignorance and carelessness which so frequently lead to total destruction of the infant's eyesight. The rules on this subject have accordingly been strengthened and a special leaflet dealing with the nature, causes, consequences, and preventive treatment of the disease adapted for the use of midwives has been prepared and circulated. The Board observes with satisfaction that there is a continued improvement in respect of cleanliness, carefulness, and observance of rules amongst midwives.

DONATIONS AND BEQUESTS.—The late Miss Caroline Catherine Williams of Falmouth has, by will, left £6000 to the Royal Cornwall Infirmary, Truro.—An anonymous gift of £5000 has been made to the Cancer Hospital, Brompton, S.W.

THE MEDICAL INSPECTION OF SCHOOL CHILDREN IN DEVONSHIRE.—At the last meeting of the Devon education committee it was proposed to increase the salary of each medical inspector by £175 per annum, in lieu of allowing any travelling expenses. They will be required to perform some additional duties, amongst these being to deliver addresses on hygiene to the children and lantern lectures for the parents.

## The Increase in Crime.

THE volume of Criminal Statistics for 1909, which has recently been issued by the Home Office, has excited a good deal of comment in the public press, not only on account of the evidence which it affords of an upward tendency in the movement of crime in this country of recent years, but also on account of the explanation of that tendency which the editor of the statistics, Mr. H. B. SIMPSON, has given in his introduction to the volume. Mr. SIMPSON, we learn from the prefatory note of Sir EDWARD TROUP, expresses in this introduction merely his personal opinion and not the official views of the department, but naturally the conclusions which he formulates must carry much weight, as being based on long experience and close study of criminal questions. Briefly stated, the main contentions advanced by Mr. SIMPSON are that there has been a steady increase of criminality during the last ten years, which is more marked than at any previous periods for which such statistics are available; that this increase must be due to the operation during these years of some cause favourable to crime, which before then did not exist at all or did not exercise sufficient influence to affect the figures; and finally, that this cause is a change in public sentiment with regard to crime, a change which, to judge from the extreme form in which it sometimes finds expression, is tending to substitute a maudlin sympathy with evil-doers for the natural and healthy reaction of a vigorous community against its anti-social elements. Of course, in any such statement of the question it is necessary to distinguish very carefully between the facts and their interpretation; and this is no easy matter, for in the complex problem of crime not only are the facts very hard to arrive at, but it is also nearly impossible to state them without some involuntary admixture of interpretative tendency. Take this very statement that crime is increasing; what it really means is that there is an increase in the number of persons tried for indictable offences or an increase in the number of such offences reported to the police; but petty larceny and murder are both indictable offences, so that a considerable decrease in the frequency of murder coincident with a more considerable increase in the frequency of petty larceny would appear by this test as an increase of criminality. And Mr. SIMPSON tells us that in fact the recent upward movement of crime is really of this relatively reassuring nature; it is an increase confined to offences of acquisitiveness, while offences of violence, on the contrary, have notably and steadily declined, and not only the offences of a gravely homicidal character, but also assaults.

At the worst, then, the increase of crime would indicate a growth of dishonesty; and before we admit even that interpretation, we have to take note of several qualifying circumstances. In 1909, for instance, pauperism was increasing, drunkenness was decreasing, and the percentage of persons fined who went to prison in default of payment was higher than for many years—all these being phenomena usually indicative of bad economic conditions amongst the class of the population from which the petty offenders are recruited. And over a long stretch of years bad economic conditions have been found to correspond roughly with an increase in crimes of acquisitiveness. Moreover, it must not be forgotten that increased density of population in itself tends to multiply the temptations and the opportunities of dishonesty, and, further, that many modern improvements and innovations create new occasions for crimes of this sort; it is notorious, for instance, that the robbing of penny-in-the-slot gas-meters has become quite an active form of criminal industry in the last few years. When due account is taken of such considerations as these, it will be seen that the increase of crime recorded of late years need not imply any real weakening of the moral fibre in the community. And if, as seems probable, these oscillations in the amount of crimes of acquisitiveness are largely dependent on economic influences, that fact in itself would tend to show that the more lenient attitude of public sentiment towards the criminal, however absurd it may be in some individual instances, is not without justification in the main. It expresses the recognition by the community of its responsibility for the acts of the evil-doer, that, in short, society has the criminals that it deserves. A community which recognises that economic conditions of its own creation, on the one hand, and, on the other hand, morally and mentally feeble adolescents for whose control and segregation it fails to provide, are important factors in its criminal problem, will naturally lean towards tolerance in penal methods. And it will be the more prone to this attitude in an age when there is a general softening of manners and a decline in the spirit of violence and brutality. The figures presented by Mr. SIMPSON show that this improvement in manners is exercising a considerable influence on the anti-social classes and is causing a steady decline in offences of violence. It is only natural, therefore, to find that it is also reacting on the attitude of society towards the criminal and is making that attitude milder and more tolerant. And though this change in public sentiment is attended with some risks, risks on which Mr. SIMPSON rightly and forcibly insists, it must not be forgotten that it is to it that we largely owe the possibility of applying to the treatment of the criminal these humane and scientific methods the initiation of which in this country has been the most notable advance in penal reform in modern days.

The proposal to treat adolescent offenders by reformatory measures, as is done to-day under the Borstal system, would have been scouted as sentimental and impracticable in times when it was confidently believed that crime could be eradicated by laws of Draconian harshness and when legal luminaries could express their intention of "putting down suicide" by penal methods. Of course, there is a danger that the sentimentalists, whose voice is always loud in the land, may exploit this public feeling so as to hinder

the full application and development of these reformatory methods by weakening the element of firmness and discipline which is essential to their success. It is easy to see evidences of this tendency in the outcry against the system of preventive detention for habitual criminals, in the slowness to utilise to the full the provisions of the Prevention of Crime Act for young offenders, and in the hysterical criticisms to which prison administration is so frequently subjected in the public press. Every protest against the emotionalism which inspires these regrettable exhibitions of flabby sentiment is rendering, we think, a genuine service to the progressive spirit on which they are a morbid outgrowth. And this is, in fact, the lesson which it is most necessary to teach at the present moment in the history of penal reform. It is not against sentimentalism that a warning is needed, but against what is the common root both of sentimentalism and of unreasoning severity—namely, the temper of ignorant emotionalism, the temper which will not let action wait on knowledge, the temper which is so eager to treat symptoms that it can never reach to causes, the temper which only sees the immediate result of action and sees that ill. This spirit, of course, works mischief in every branch of social policy, but hardly anywhere has its influence been more pernicious than in regard to the treatment of crime.

## An Act of Homage to a Medical Martyr.

IN compliance with an order issued by the President of the Mexican Republic a marble memorial stone was uncovered in the National Bacteriological Institute of the City of Mexico by the State Secretary of Public Instruction and the Fine Arts on June 24th, 1910, as "an act of homage" to the memory of Dr. HOWARD TAYLOR RICKETTS, who died on May 3rd, having fallen a victim to typhus fever while carrying out important scientific investigations into that disease in the city. As a further recognition of the benefits which Dr. RICKETTS'S work had conferred upon the Mexican nation the President commanded the publication of a commemorative volume in which is given a portrait of the deceased, together with an account of the ceremony and the orations delivered by certain distinguished persons when the memorial stone was uncovered. The volume, which is printed in Spanish, reproduces five papers written by Dr. RICKETTS, mostly in collaboration with his countryman Dr. RUSSELL M. WILDER, on the subject of Mexican typhus, locally known as "tabardillo," four of which have already appeared in the *Journal of the American Medical Association*. By further order of the President the volume has been sent, not only to the Mexican scientific institutions, but also to the principal universities, scientific societies, libraries, and medical publications of those countries which are friendly to Mexico. Dr. RICKETTS at the time of his death was 39 years of age; he had graduated at the University of Chicago in 1894. After holding a number of hospital appointments he spent a considerable time in post-graduate study in Paris, Berlin, and Vienna. In 1903 he was appointed an assistant professor in the University of Chicago, and shortly before his death he accepted the offer of the chair of pathology in the University of Pennsylvania. In 1906 he made an investigation into the disease known as the spotted fever of the Rocky Mountains, and showed himself to be an investigator of the first rank. Subsequently, his attention having been directed to the close clinical resemblance between this spotted fever and Mexican typhus, he proceeded to Mexico to conduct his researches on the spot, utilising with the consent of the authorities the clinical resources of the hospitals, as well as the scientific facilities of the laboratories of the bacteriological institute. Anyone who has had the opportunity of examining month by month the statistical reports of the city of Mexico must have been struck with the amount of "exanthematic typhus" recorded there year after year. To prevent the suffering and loss of life occasioned by this malady Dr. RICKETTS undertook his investigations. His observations demonstrated that the disease is not infectious in the ordinary sense, but that it is conveyed by the bites of the body louse (Pediculus vestimenti). This fact alone points out how the infection may easily be prevented, and must prove of the greatest service to the Mexican people. Shortly before his death Dr. RICKETTS announced that he had found in the blood of typhus patients a bacillus which he believed to be the specific microbe of the disease. It is not certain whether the typhus fever of Mexico is the same as that which is found in the Old World. Observations made by Dr. CHARLES NICOLLE in Tunis gave somewhat different results to those obtained by Dr. RICKETTS, but the mode of transmission is precisely the same, and this has been further established by the work of Dr. JOHN F. ANDERSON and Dr. JOSEPH GOLDBERGER of the United States Public Health Service. We are not here concerned at present with the claims of the different investigators to priority in the discovery of the mode in which typhus fever is spread. It is enough for us that Dr. RICKETTS demonstrated the mode for the Mexican form of the disease, and for this alone he has earned the lasting gratitude of that nation. His death adds one more name to the long list of medical heroes who have given up their lives in the search for knowledge by which their fellow men were to be benefited.

## The London County Council and the Inspection and Treatment of School Children.

EARLY in December, 1910, the annual report for 1909 of the chief medical officer of the Board of Education was presented to Parliament, and in our review of it we stated that it was a document of great interest and extremely cheerful tendency, but we noted at the same time that Sir GEORGE NEWMAN had been compelled to point out that as far as the medical inspection of children was concerned the County of London lagged behind the rest of the kingdom. The complicated difficulties under which the London County Council has found itself in the matter of education are, many of them, well known to all our readers, and there is no reason to doubt that the Council has in many directions made vigorous effort to deal with these difficulties. Mr. R. BLAIR, the education officer, is struggling

manfully with an elaborate system of organisation the whole blessings of which are not yet obvious to those who are considering education from a general point of view, while the facts are indisputable both that too large a percentage of the children in London are not systematically inspected and that too large a percentage of those inspected escape subsequent treatment. The words of the chief medical officer of the Board of Education, in the report to which we have alluded, conveyed a distinct warning that the London County Council, in the matter of its educational functions, would be required to mend its ways, and a good many of our readers must by this time have asked themselves when the necessary reforms would begin to take place. Medical inspection of school children has now been an integral part of the public health administration of the country for some two years, having become a statutory duty upon local education authorities as far back as the passing of the Act of 1907. There is nothing unreasonable in saying that there ought by this time to have been worked out for the metropolis by the London County Council an adequate scheme of medical inspection, and some system of consequent treatment.

We are bringing these conclusions to public notice being perfectly aware that the Council itself does not consider that the treatment of school children has been properly dealt with. At the meeting on Feb. 14th there were open manifestations of the differences of opinion which are known to exist among the members of the Council as to the course to be adopted. At this meeting among the proposals for increasing the salaries of the principal officers was one to raise the salary of Mr. BLAIR, the education officer, and one of the reasons given by the General Purposes Committee for its recommendation to pay this emolument to one of its servants was the growth of that part of the education service which might be summed up in the phrase, "the care of the child." Medical men will be the first among ratepayers to support the provision of adequate sums in respect of the education of the children of London, but they will ask themselves anxiously whether "the care of the child" in this connexion means his medical welfare, and if so whether the education officer was appointed with any recommendations for medical knowledge which he is now expected to display in return for an enhanced salary. It now seems clear that under one course of procedure the education officer may be invited to supervise in some way the inspection and treatment of the school children under the care of the Council, inasmuch as the existing condition of things is admittedly unsatisfactory; and that the situation was thus interpreted was proved by the suggestion of a member of the Council at the meeting on Feb. 14th, that as a result of deliberations now proceeding in committee Mr. BLAIR might be relieved of work of this nature, inasmuch as it might be coördinated under the Public Health Service. The remark went to the root of the matter. Three courses lie before the Council and are quite definite. It can leave matters as they are; it can invite the education officer to supervise the medical inspection and treatment of school children; or it can follow the course which has been successfully taken by the majority of the educational authorities in the kingdom and place the inspection of school children in the department of the medical officer of health. Over a year ago, out of 314 instances where school medical officers had been recognised by local education areas, the medical officer of health had been selected to act as that officer in 230 cases, and the practical coöperation between the medical officer of health and the education medical officer has proved generally—indeed, as far as we know, universally—to result in good work. With regard to leaving matters as they are, the Board of Education seems likely to have a good deal to say against the adoption by the London County Council of such a course, and it is known that the Council does not lean to this apathy. The attitude of the Government Department towards the London County Council was for a long time one of consideration. The difficulties to be encountered in organisation were recognised, and it was not until it became practically public property that the London County Council was unable to administer satisfactorily one of the statutory duties of a local education authority that the Board of Education, as its duty was, began to insist upon reforms being undertaken. We feel certain that the London County Council, against the virtue of whose intentions we are alleging nothing, has come to the conclusion to make a move in one of the other two directions that lie before it. It will construct for the medical inspection and treatment of school children a scheme under the supervision of the education officer, or it will make such inspection a branch of the general health administration of the county. A report from the Children's Care Subcommittee has been, or shortly will be, laid before the Education Committee of the Council recommending that the work, at present under the direction of the medical officer for education purposes, Dr. J. KERR, should be placed under the supervision of Mr. BLAIR, and it remains to be seen how the Council will act thereon

To place the medical officer of the London County Council for education purposes directly under a lay authority is to run great risks that the Act of 1907 will not be administered in accordance with the purposes of legislation. The medical inspection of school children is a medical affair as well as an educational affair—this the most enthusiastic educationist must admit—and while it is as closely as possible connected with sanitary administration, it is only loosely allied to general pedagogy. We know perfectly well that in earlier days there was no universal adherence among medical men to this view; the matter is obviously one of opinion, but opinion has become now, we think, unanimous. Moreover, those who lay stress upon the medical side of medical inspection are in the advantageous position of pointing to the existing and satisfactory organisation of the sanitation of the country as affording machinery for the actual work; while those who would separate the inspection of school children from the public health service have to devise some other scheme. The subcommittee of the Education Committee at the present moment is apparently taking the view that its medical officer for education purposes is a more natural ally of its education officer than of the chief medical officer to the Council. To us it seems inevitable that sooner or later the inspection of school children will become a

department of the general health service, whose finished and comparatively ancient organisation is quite able to expand in the direction of the necessary duties. There may be an attempt to keep the two things apart, and such an attempt may be successful for a time, but, rash as it is usually to prophesy, it is fairly certain that in the end there will be a union. We confess that we wish the Council would ratify that union at once.

# Annotations.

"Ne quid nimis."

## THE PATHOLOGY OF THE ONLY CHILD.

THE vagaries and caprices of the only child are almost proverbial, but so far they have attracted but little notice in text-books on pædiatrics, though they are well known to most experienced practitioners. Dr. Joseph K. Friedjung of Vienna contributes an interesting study of this subject to the *Wiener Medizinische Wochenschrift* of Feb. 4th. He states that practically the only references he has been able to find to it are those by Czerny and Neter, both of whom deal chiefly with the defective development of character which seems to occur in some of these children. Dr. Friedjung bases his observations upon 100 children who were the only offspring of their parents, whom he has studied in his private practice. The cases were not selected but simply taken chronologically. There were 45 boys and 55 girls; 86 of them were between 3 and 11 years of age, 9 between 11 and 15, the remaining 5 being under 2 years. Of the 100 children only 13—viz., 6 boys and 7 girls—could be described as normal; the remaining 87 proved to be neuropathic in organisation in greater or less degree. For comparison Dr. Friedjung studied the nature of 100 children from families with numerous children also casually collected. Of these 69 proved to be normal and only 31 showed neuropathic tendencies. Of the 87 "nervous" only children 18, comprising 7 boys and 11 girls, were severely affected. In general, the girls showed the more marked changes. The manifestations are divided by Dr. Friedjung into general and local. He refers, first, to the mental characteristics of the only child, as described by Neter, especially to his nervousness, lack of self-reliance, precocity, vanity, egotism, and unsociability. One special feature is often extreme timidity, even to the extent of morbid terror. This symptom was present in all but 12 of the 87 children showing abnormal conditions. They were often afraid of dark rooms and of sleeping alone. Occasionally they were nervous of loud noises and of certain animals, though not necessarily of large ones like horses and dogs. In close relation to these morbid fears was the restlessness at night, from various degrees of which up to actual night terrors 49 of these children were found to suffer. Capriciousness and peevishness were complained of spontaneously by the parents of 7 of the boys and 12 of the girls in this series, and on inquiry these characters were found to be present in the majority of the remaining cases. Precocity or too rapid evolution of the intellect was the rule and present in all but 9 of the 87 nervous children, and was also observed in 5 of the 13 normal cases. Thirty-three of the 100 children were brought to Dr. Friedjung for defects in nutrition. Many of them were pale, of weak muscular development, and had but little subcutaneous adipose tissue. In many cases this appeared to be due to severe anorexia, from which 50 of the 87 abnormal children suffered. As many as 37 of them suffered from habitual vomiting and 20 from chronic constipation. Frequency of micturition, apart from cystitis or any abnormality of the urine, was a commonly observed symptom, and enuresis was recorded in 10 boys and 2 girls. Lichen urticatus occurred in 26 boys and 22 girls, and 16 of these were much distressed by the itching produced. Dr. Friedjung is of opinion that diseases with a nervous factor such as pertussis run a more severe course in many of these children, but believes that the supposed severity of many other complaints, as they fall upon only children, is apparent rather than real, being, in fact, an exaggeration on the part of the anxious parents. Dr. Friedjung discusses the causation of the peculiarities he has observed and recorded in his paper. He agrees in the main with Neter's suggestions—viz., that they are due to over-education and to the lack of the influence of brothers and sisters—but he points out that these are not the only factors, since he maintains that the favourite child of large families may show similar peculiarities. His observations are certainly of interest and constitute an addition to our knowledge of the subject which should stimulate further study of the characters of these children.

## HOW TO IMPROVE LONDON'S TRANSPORT.

BEFORE the days of the Bankers' Clearing House we are told that about 40 bankers called individually upon one another, making altogether about 1560 visits in the day. Now the same exchange of business can be accomplished by a single call from each banker at the Clearing House, making altogether 40 visits in the day. Mr. A. W. Gattie proposes to apply the same principles to the handling of goods and parcels and to establish a central goods clearing house in London, where about 100,000 tons of goods could be dealt with in the day with the consequent saving of time and labour that follows good organisation. The necessity for such organisation becomes apparent when we are informed, upon the evidence of facts and figures, that recent increased locomotive power in our railway engines coincides with a decrease in their earning power, and that this is due to the difficulty experienced in transference and handling of goods on account of the badly arranged goods railway stations, and that there are in use in London streets twenty times as many goods vans as are necessary for the work required to be done. In a lecture which Mr. Gattie delivered before the London Chamber of Commerce last July, entitled "How to Improve London's Transport," he outlined the scheme of a goods clearing house. With this report and with the help of an article which appeared in a subsequent number of *The Electrician* some idea can be got of the ambitious scheme which is on foot, and is expected at an estimated cost of £6,000,000 to deal with London's transport and free its streets from 25 per cent. of the total vehicular traffic—viz., that made up of loitering vans and other slow-moving vehicles, thus adding an estimated road space of 33 per cent. of the existing area to the metropolis. The traffic problem will not then seem so pressing. The scheme has a humanitarian and a medical interest, in that its accomplishment will lessen the work of the hospital accident and casualty department, where a large proportion of the serious street injuries dealt with are occasioned by vans and other slow-moving, heavily laden vehicles. The method which it is proposed to adopt is the establishment of a single large depôt or "clearing house," accessible for all railways by underground tunnels, and from the port by means of a tunnel connecting a river wharf with the clearing house. The goods received by rail, road, and river would be sorted for delivery by means of ingenious electrical and mechanical

appliances, and would be distributed over the metropolitan area by a number of motor vehicles. The worst feature of vehicular traffic carrying goods is its lengthy occupation of road space, for standing vehicles form a fixed obstacle to all other traffic, and it is this kind of street difficulty which would at once be removed by the employment of the particular pattern of motor van which it is intended to use to serve the goods clearing house. The van would be provided with a detachable "container" which could be hoisted out of the van into a building by means of a crane, and another container loaded with miscellaneous goods for despatch to various destinations substituted. The double operation with the aid of a suitable crane could be accomplished in about four minutes. Sorting at the clearing house is to be accomplished by means of "belts" or moving platforms fitted with electro-magnetic apparatus which enables them to receive or discharge loads which are deposited beside them on suitable magnetic trays or tables, and by means of an instrument called a controller they are able to do this in a way predetermined by the operator. The result is achieved by the use of reciprocating roller magnets which revolve at the same speed, one set being fixed at the station, the other set being carried by the moving platform. An undertaking of this character and comprehensiveness is one which London might be proud to accomplish. Unlike many private enterprises, this is one which will benefit the public as well as the shareholder, and provide a means of reducing the congestion in our streets at no expense to the ratepayer—a result which everyone will welcome.

## ACUTE SYPHILITIC MENINGITIS.

THE change in view point from which the modern observer regards the relation of syphilis to diseases of the central nervous system is reflected in the general review which Dr. Marcel Miriel gives in the *Gazette des Hôpitaux* of Jan. 7th of the recently differentiated nosological syndrome "acute syphilitic meningitis." The inevitable sequel to the acceptance of syphilitic nervous disease as an infection *viâ* the meninges is the correlation of syphilitic meningitis with other forms of meningitis. For 40 years previous to the important researches of Widal, Sicard, and Ravaut on the cerebro-spinal fluid the reality of acute syphilitic meningitis was questioned by many competent observers; but when in the year 1900 it was conclusively demonstrated that cytological changes in that fluid accompanied meningeal reactions to infective agents, it was felt that a diagnostic criterion had been established by the aid of which the genuineness of acute syphilitic meningitis could be effectively proved. Since that date abundant clinical and pathological evidence has been forthcoming whereby it is easy to-day to furnish a text-book description of a definite form of acute meningitis which is syphilitic in origin, and which can be distinguished from acute tuberculous, or septic, or epidemic cerebro-spinal, or any other variety of the disease. In the great majority of cases acute syphilitic meningitis is preceded by cutaneous manifestations of the infection that are particularly severe. Sometimes there is a definite parallelism between the two, so that the meningeal reaction has been described as a meningeal exanthem. It is during or soon after the appearance of the secondary symptoms that meningeal involvement reveals itself, first of all by the prodromal symptoms of headache and insomnia. The former is continuous, diffused, intractable, and subject to nocturnal exacerbations. Occasionally it is so persistent in its severity as to dominate the clinical picture completely. Insomnia is very common, and ought always to be made a matter for inquiry. At this initial stage there may be little else to attract attention, and even when the syphilitic meningitis is established the paucity of its clinical accompaniments is one of its distinguishing characteristics. Stiffness of the neck is less marked than in other varieties of meningitis. Kernig's sign is common. Convulsions are rare. Palsies are very rare indeed, with the exception of the highly important ocular palsies, notably the third nerve. Fever is by no means frequent; in fact, Dr. Miriel considers it is usually transient and has reported a large number of cases in which it has been awanting. The patient is rarely as affected mentally as in the ordinary forms of meningitis; though suffering from severe headache he will talk lucidly of his illness; he practically never has a meningeal facies. Thus acute syphilitic meningitis is characterised by the restricted nature of its symptomatology, although each and all of the accepted symptoms of meningitis may be detected in any particular case; the moderate type is much more frequently encountered than the advanced. In proportion to the degree of the meningeal implication the comparative mildness of the symptoms, apart from the headache, constitutes an important aid to diagnosis. The cerebro-spinal fluid is almost always clear, free from bacterial infection—some observers have found the treponema in it—and under the microscope reveals an abundant lymphocytosis with occasionally a varying degree of polynuclear leucocytosis. The lymphocytic reaction may be found before any clinical symptoms whatever of meningeal inflammation can be detected, and it may persist after these symptoms vanish. Hence the examination of the fluid is of the utmost significance, for its clear and amicrobic character, coupled with the lymphocytosis, is almost pathognomonic. Treatment by repeated lumbar puncture is often of the greatest value. Dr. Miriel has used intravenous injections of one or even two centigrammes of mercury daily with striking success. He merely mentions "606," the matter being *sub judice*, and says little of serum diagnosis.

## CANNED GOODS AND THE PUBLIC HEALTH.

THE report which Mr. Otto Hehner, analyst for the county of West Sussex, has recently presented to the county council points out the desirability of legislation dealing with the canned goods trade. During last quarter he analysed seven samples of preserved (tinned) lobster and seven samples of preserved (tinned) salmon for the purpose of detecting the quantity of metal that had been dissolved off the surface of the canisters. The following was the result expressed in grains per pound:—Lobster: 1·28, 0·27, 0·12, 4·47, 0·80, 0·51, and 0·09; salmon, 0·46, 0·21, 0·77, 0·24, 0·51, 0·38, and 0·35. These figures show that preserved (tinned) salmon is preferable to lobster, but Mr. Hehner explains that the quantities of tin dissolved in the salmon are comparatively small, probably because the oil in which the salmon is packed to some extent protects the surface. The quantity of contamination increases with the age of the goods, because the acid juices continue to act upon the metal. In course of time, therefore, all such preserved goods as are capable of attacking tin will contain an important quantity of the metal. Such materials are all meats and fruits; not condensed milk or syrup. The fixation of an age limit seems advisable. The date of packing ought to be compulsorily stamped on each can. It would be easy to ascertain when the maximum tolerable quantity, suggested by the Local Government Board at 2 grains of tin per pound, has been reached, but it would vary with the acidity of the material. The suggestion that the date of packing the goods should be clearly indicated on each can is an excellent one, and one which could easily be introduced. Dr. G. S. Buchanan and Dr. S. B. Schryver, on behalf of the Local Government Board, a year or so ago, were not able to gain any decisive evidence that tinned foods caused bodily harm attributable

to tin salts, but it seems a pity that the simple precaution of lining tins with an innocuous varnish is not very generally adopted.

## INFLUENZA AT THE VATICAN.

OUR Roman correspondent writes, under date Feb. 18th :— "Influenza has made a pilgrimage to the Apostolic Palace and has been 'received' by the Holy Father, by Cardinal Rampolla, and by Cardinal Rinaldini. Dr. Petacci, body-physician to his Holiness, was thereafter in prompt attendance, and the Pope, responding to treatment, may now be regarded as convalescent. Exaggerated announcements as to complications, bronchial and other, have been reduced to their proper dimensions by the official press, inspired by Dr. Petacci himself. The postponement of receptions till next week has been *motivé* as a measure of precaution, considering the advanced age of his Holiness, as also the rigour of the season and the danger of infection imported from without. It is from this latter source that the unwelcome visitant has effected admittance, so that until the public health has returned to its normal standard the surveillance imposed at the Vatican on all 'arrivals,' official and non-official, will lose none of its strictness. Meanwhile Cardinal Rampolla's condition causes some anxiety, due to the high temperature and the characteristic pathognomonic signs. Cardinal Rinaldini, too, is not out of danger. For some days confined to bed, he is still feverish enough to require vigilant attendance, as, at no time robust, he has recently betrayed symptoms not conducive to rapid or permanent recovery from infective disease."

## RUPTURE OF THE LARGE INTESTINE DUE TO COMPRESSED AIR.

COMPRESSED air is used commercially for a great number of purposes, including riveting, working small tools, blowing away the filings in rapid lathe work, cleaning engines, &c. It is piped round buildings and applied, like water, through a hose under a pressure of from 40 to 125 pounds per square inch. Its use is much more common in the United States than in this country, and it is not surprising, therefore, that the cases recorded in *Surgery, Gynæcology, and Obstetrics* for January by Dr. Andrews, where this medium has been the cause of several fatal accidents, should be entirely of American origin. Dr. Andrews's case was that of a man admitted nearly moribund, cyanotic, gasping for breath, enormously distended. His neck and chest were emphysematous; the abdomen was globular, tensely inflated, and free air could be felt crackling in both groins. The thorax was rigidly set, respirations were 46 to 52, and the pulse was small, hard, 114. The history was that he was using the air-hose to blow the sawdust off his clothes, and that some of his companions, in jest, caught the hose and pushed it towards his nates. The hose had no nozzle; it was an ordinary flexible $\frac{3}{8}$th inch tube, with a pressure of 60–65 pounds. The tube did not get within an inch of his trousers; nevertheless, with the pressure so high, the column of air several inches in advance of the tube was sufficient to force the anal sphincter as if it had been a solid body. With this history to guide them the surgeons attempted to relieve the pressure by passing a rectal tube. This, however, gave no relief, and accordingly the abdomen was opened, a puncture wound being made in the middle line in front. There was an immediate rush of gas, the abdomen was allowed to empty itself gradually, and the condition of the patient improved so much that an exploratory operation was considered safe. Five hours, therefore, after the accident the abdomen was opened. It was then found that the peritoneum was soiled with fæces, and that the sigmoid flexure was ruptured along its convex border for nearly six inches. The tear was mainly in the serous, muscular, and fibrous coats, the underlying mucous membrane bulged and was torn in three places, showing that it had herniated through the tear in the fibrous layer, ruptured, and then retracted. The ruptured portion of the sigmoid was excised, the ends inverted, and a lateral anastomosis performed. The patient was treated by continuous saline irrigation, and gauze drains were inserted for a few days. Eventually he recovered. Since his attention was thus drawn to the condition, Dr. Andrews has been able to collect details of 15 more cases in the practice of American surgeons, and several useful conclusions can be drawn from them. The air-hose is not dangerous in itself, turned on most parts of the body it produces a stinging effect only. The accidents seem almost wholly to have been due to other employees turning the hose, as a practical joke, towards the victim's anal region. It need not be applied directly to the anus, and the fact that the victim is wearing his clothes is no protection. The nates form a hollow cone of which the anus is the apex, and compressed air expanding in this cone forces the anus without direct application. The bursting-point of the large intestine is probably from 6 to 10 pounds when *in situ*. The rupture is most common in the sigmoid, probably because it is the first unsupported portion of large intestine reached, and also because the rushing air is confined momentarily in the loop. Rupture is, however, sometimes multiple; the splenic flexure has been found the first portion torn, and in one remarkable case that died the sero-muscular coat from the rectum to the cæcum was split, but the mucous membrane though herniating through had managed to remain intact. With regard to the mortality, this, as might have been expected, is at present very high. Of the 16 cases recorded, 13 died. Of these, 7 were submitted to an exploratory laparotomy, with 4 deaths. On the other hand, of the 9 not operated on, all died. None of the cases appear to have been diagnosed apart from the history. Several were treated as "colic" till the details were extracted. It is probable, however, that in future, now that the characteristic features of the condition have been emphasised, diagnosis will be more accurate, and operation, therefore, more rapidly decided upon.

## THE LIGHTING OF SCHOOLS.

AT a meeting of the Illuminating Engineering Society held on Feb. 16th a discussion on the lighting of schools was opened by Dr. James Kerr, medical officer (education) to the London County Council, and Mr. N. Bishop Harman, oculist to the London County Council Education Department. The former confined himself to daylight illumination and described methods for obtaining measurements of sufficient accuracy to ensure good illumination in the worst lit parts of the rooms. He dwelt upon such details as the relation of window area to floor space, the colour of the walls, the disposition of the desks, the elements concerned in retinal and mental fatigue, and so on. Mr. Harman dealt with artificial lighting. He described his experience in visiting various London schools, and emphasised the need for properly designed shades so as to screen the eyes and throw the light where it was wanted, and distribute the light uniformly over the desks and the blackboard. He showed by means of diagrams how different arrangements of lights enabled this to be done, and how glare in the eyes of the children and inconvenient shadows could best be avoided. The President, Professor S. P. Thompson, in his opening remarks, pointed out the good work that was being done by the Illuminating Engineering Society in bringing together the lighting engineer, the architect, and the medical officer, all of whom

ought to have their voice, and coöperate in arranging school lighting. A feature of the discussion was the presentation of the results of a series of measurements of illumination in typical schools in London. At the next meeting of the society on March 14th the more technical aspects of school lighting will be dealt with, and further data gathered in a large number of schools and colleges will be presented.

## THE TRANSVAAL MINING COMMISSION.

THE late Transvaal Government in 1907 appointed a Commission to inquire into mining conditions generally in the Transvaal. Although the Commission submitted its final report in March, 1910, it has only recently become accessible. Its findings in the main are very sound, but all its views will not be accepted by the medical profession, particularly the very low estimate of air-space—200 cubic feet—which is considered sufficient for a native living in a "compound." Nothing can be better than the recommendations of the Commission on the matters of a constant supply of clean water for laying the dust of mining operations, the erection of proper shelters at the shaft-head for underground workers and the prohibition of erection of back-to-back dwellings, and the laying down of a standard of purity for air in the mine-workings.

## CANCER DEATH-RATES: A STATISTICAL STUDY.

WE have received from Mr. G. D. Maynard, F.R.C.S. Edin., of Pretoria, a reprint of his paper on the Statistical Study of Cancer Death-rates, which has appeared in our contemporary *Biometrika*. The etiology of cancer is still a mystery. We therefore welcome Mr. Maynard's present contribution, which approaches the subject from the statistical side, and is based on data not ordinarily accessible in this country. The writer admits, *in limine*, the imperfections that are inherent in death-rates not based on post-mortem examination, but he questions the wisdom of disregarding them entirely as valueless because of their lacking absolute correctness. One must remember, he insists, that in dealing with large masses of figures the errors in excess tend to compensate for those in defect, wrong inclusions in a group in this way counterbalancing accidental exclusions. In this connexion Mr. Maynard appropriately suggests that the value of death-returns would be greatly enhanced if the registrars would add separate tables of the causes of death concerning cases in which the diagnosis has been confirmed by necropsy. In opposition to the theory that much of the undoubted increase in the recorded mortality from cancer is due to improved diagnosis, the writer points out that when the occupational cancer-rates are examined the wealthier classes, although better provided with skilled medical aid, and therefore, presumably, undergoing a stricter process of diagnosis, show the lowest cancer death-rates, while distinctly higher rates are observed among the labouring and agricultural classes. This is the reverse of what might have been expected if the explanation were the true one—that better diagnosis accounts for the increased rate. When first approaching the study of the present problem the writer tells us that, in spite of the trend of modern research, he inclined to the view that the infectious nature of cancer might eventually be demonstrated and that it was either bacterial or protozoic in nature. But subsequently finding that the theory of infectiousness gained no support from his investigations it occurred to him to correlate the rates of cancer with those of diabetes mellitus, the reasons for this decision being as follows: (*a*) the etiology of both diseases is obscure, and they have similar age-distribution; (*b*) they stand almost alone as being on the increase, whilst practically all other diseases show a decrease. The whole essay is replete with formulæ and with tables too numerous for insertion here, and we hesitate to publish a portion of them only for fear of confusing our readers. For full consideration of the statistics we must therefore refer to the original paper.[1] At present we content ourselves with indicating some of the conclusions at which the writer has thus far arrived, and we join him in expressing the hope that the publication of the paper may encourage helpful criticism, and thus enable future work to be more profitably planned. The more important of Mr. Maynard's conclusions are to the following effect: (*a*) That the statistics already dealt with by him give no support to the suggestion that cancer is of infectious origin; (*b*) that whatever theory as to the causation of cancer is adopted some explanation is required of the remarkable correlations between cancer, diabetes, and insanity; (*c*) that the following may be suggested as a probable explanation of the facts as disclosed by statistical analysis—viz., that conditions of modern life, acting on physiologically unsound material, may account for the correlations existing between these three diseases—correlations which are not fortuitous or due to erroneous observation. The increasing mortality of cancer may also be accounted for in the same way.

## THE TYRANNY OF THE TELEPHONE.

BEFORE the introduction of the telephone it was the general habit of medical men to permit no interruption of a consultation for anything short of an imperative necessity. Once the patient was in the consulting room the practitioner's undivided attention was given to that patient until the close of the consultation; and trivial messages and communications had to wait until the medical man was at liberty to attend to them. Now, however, with the telephone on every desk it is no uncommon thing for a consultation to be frequently interrupted while queries are answered from some other patient, or appointments made, some of which may even have no bearing on professional work at all. Many patients resent this, and we think not unreasonably; and in the matter of one well-known consultant formal complaint has been made to us. Surely it would be more fitting on the part of consultants to entrust the telephone during consultation hours to an assistant who could decide whether messages should be brought immediately under the notice of his principal, or should await the termination of a consultation in progress, as in former days verbal messages, notes, or callers had to do. The situation is not so common in the routine of general practice, and here it may be to some extent inevitable, but as far as possible it should be guarded against. Urgencies are no more urgent to-day than they were then; while trivialities should not be allowed, because they are discussed by telephone, to assume a precedence which would be denied to an attempt to intrude them by verbal message, note, or personal interview.

## THE GENERAL INFIRMARY AT LEEDS.

ELSEWHERE in this issue we print the report of a meeting of the citizens of Leeds at which it was decided to take steps to commemorate the reign of His late Majesty King Edward VII. by raising a fund for the purposes of the General Infirmary at Leeds, which stands urgently in need of £150,000 for extensions and for maintenance. In the early days of the Leeds Infirmary the claim which it had upon the public for support was the moral one—that which the sick poor have always upon those who are better off; but to this are added to-day the claims of an institution to which few families in Yorkshire do not owe a

[1] Biometrika, vol. vii., No. 3, April, 1910. Cambridge University Press.

personal debt. With her infirmary and medical school, now part of a great University, Leeds may fairly claim to have played an important part in the progress which has been made in medical and surgical science in recent years, and to be capable of taking her full share in the work of the future. Whether, therefore, Yorkshiremen are guided by enlightened self-interest, by feelings of devotion and loyalty to the memory of the late King, by the more enduring and deeper feelings of sympathy with the poor and needy, or by the desire to repay the infirmary for benefits received, there can be no more worthy manner of expressing these feelings than by a ready and adequate response to the appeal which is being made to them on behalf of the Leeds General Infirmary by the Lord Mayor of Leeds.

## LIFE ASSURANCE MORTALITY RECORDS.

THE records of life assurance offices contain a mass of data bearing on the incidence of fatal disease which is seldom made available for the purposes of general medicine. At the last meeting of the Life Assurance Medical Officers' Association on Feb. 1st a paper was read by Dr. R. Hingston Fox on Mortality Records of Assured Lives. A schedule was submitted for use in the offices upon which all deaths could be entered according to the cause and the age attained. In the discussion which followed the reading of the paper opinions differed as to the use of such records in practical life assurance work, but their value in general medicine was acknowledged. The construction of the detailed schedule of diseases followed the lines of the Bertillon list, modified and expanded for the purpose. This list, which has just been adopted by the Registrars-General of the three kingdoms, has not given unmixed satisfaction to pathologists, as our own columns have shown.[1] Sir John W. Moore is not alone in his grave doubts of the expediency of putting back among local disorders the infective diseases which the Royal College of Physicians of London had placed with their epidemic congeners. On the other hand, there is an obvious and strong motive in conforming to a list which has now been accepted by nearly all the civilised countries of the world as is the case with that of M. Bertillon.

A SMART little outbreak of small-pox has taken place in the Mile End Union area, the first case being diagnosed in the Mile End Infirmary.

THE Morison lectures on Melancholia (the depressive phase of manic-depressive insanity) will be delivered before the Royal College of Physicians of Edinburgh by Dr. George M. Robertson, on March 6th, 8th, and 10th, commencing each day at 5 P.M.

THE hearing of the action brought by Mr. C. R. Thomas against Mr. H. A. Barker, bone-setter, of Park-lane, for damages for negligence in the performance of operations, which were alleged to have led to the amputation of the plaintiff's leg, resulted in the verdict of a special jury for the plaintiff for 20 guineas, judgment and costs being given accordingly

[1] THE LANCET, Jan. 21st, 1911, p. 189.

MEDICAL SOCIETY OF LONDON.—Dr. F. S. Palmer's paper on "Traumatic Neuroses and Psychoses and their Medico-Legal Consideration," which should have been read before this society on Feb. 13th, was postponed. It will be read on April 10th, when papers will also be read by Dr. F. Parkes Weber and Dr. C. W. Chapman.

# MOTORING NOTES.

BY C. T. W. HIRSCH, M.R.C.S. ENG., L.R.C.P. LOND.

*The 10-h.p. Four-Cylinder Darracq Two-Seater.*

ALTHOUGH for four-seaters the modern tendency to employ engines of a very low power is somewhat overdone, there is no doubt that for a two-seater a low-powered engine is the ideal, and therefore this car, the latest production of a firm which has always given attention to the needs of the profession, is worthy of attention as a car for professional use. The engine has four cylinders, cast *en bloc*, with a bore of 68 mm. and a stroke of 120 mm., and as a result of this long stroke the pulling power is good. It also has this advantage, it comes under the £1 11*s.* 6*d.* tax. The valves are all on one side and operated by an easily withdrawn cam shaft. Ignition is by a Bosch high-tension magneto, but though this rarely gives trouble, I must say I prefer a dual method of exploding the mixture, which on this type can be fitted as an extra. If a plug is sooted or fails it is easier to use the switch than the spanner. The firing point is fixed, and thus all ignition timing levers are dispensed with, and with a car of this power the want of a method of altering the ignition point is not felt. Cooling is assisted by a fan placed behind the radiator, and the water is circulated by a gear-driven pump. The water-pipes are of generous size, and the clips used for gripping the rubber tubing are satisfactory. This is, I know, a small point, but from experience I have found out how essential it is that these little accessories should be perfect. To have to fix a broken rubber hose with string or copper wire is worrying, and the advantage of substantial water-pipe clips, like other trifles that are not always found on cheap cars, is great. Lubrication is by a plunger pump in the base chamber, which can easily be withdrawn by unscrewing a plug in the bottom of the crank-case. An oil tank is fitted behind the dash under the bonnet, and in view of the driver on his side of the dash is an adjustable sight drip, which regulates the amount of lubricant delivered. The carburettor is of the latest Darracq type, it is very simple, and permits of the jet being withdrawn in a few seconds. From the float chamber to which the petrol comes by gravity, the jet projects at right angles, and over the latter is the choke pipe that conducts the mixture through a foot-controlled throttle to the inlet valves. So many carburettors are a source of worry, that I welcome this type, as with it complications seem impossible. It is also economical, as I found the car do from 25 to 27 miles to the gallon of petrol, and another characteristic is the ease with which the engine can be started, even the first thing on a frosty morning, after the car has been standing all night. The transmission is by a leather-faced cone clutch with spring buffers to a gate-controlled gearbox, provided with three forward speeds and a reverse, and then by a Cardan shaft with two universal joints to the usual live axle. I had the opportunity while at Walnut Tree Walk of seeing one of these taken to pieces, and was greatly impressed by its simplicity and strength; the differential, too, appeared a sound engineering job, and provided that plenty of grease and oil is placed in the crown wheel casing, these parts should be free from breakdown and, what is more, have a very long life. A thrust ball-bearing is fitted on the crown wheel, otherwise the bearings are of the plain kind, and provided that during the first few runs plenty of grease is supplied to the shafts, to which the back wheels are fixed, they answer very well. On the trial car lent me, I found these bearings, even after an 80-mile run, perfectly cool. The front wheels also run in plain bushes, grease cups providing ample lubrication. The steering gear is of the irreversible pattern, and I found it easy to use and quite free from any loss of motion between the hand wheel and the steering axle. Three brakes are supplied, one pedal applied, acting on the Cardan shaft, and two others controlled by the hand lever, and taking effect upon the back wheels. All are of the internally expanding variety and well provided with means of taking up wear, and designed so that when required new shoes can easily be fitted.

A good many objections have been made to accelerator pedal control, but this has always been because it was in an uncomfortable position; here it is in the most convenient place, with the result that I am sure all will be satisfied with this

easy method of control. I took the car from Walnut Tree Walk and drove through the City. There are occasions on driving a small car in traffic when the engine, after a halt behind slow-going vehicles, falters if asked to pick up again on the top speed; this was not in evidence with this car. In fact, the nicety with which it could be controlled and the refined manner in which the power was developed, impressed me greatly, and certainly gave me the impression that it was an ideal mount for the doctor who drove himself. And yet I had a bad night's rest as a consequence of my drive. While in the Commercial-road there was a halt in the traffic, in front was a van, behind me another, and on each side more vehicles; the brakes stopped the car at once, but I was hemmed in, with the result that when the front van backed the test car's front mud-guard acquired a fantastic and morbid form. The fault was, of course, not mine, and as I was not sure if Messrs. Darracq had insured this car I dismounted to obtain the usual particulars in view of a possible action for damage; this entailed the presence of the police, and later on I heard that they wanted the name of the car owner, and then I discovered that as I was driving with trade numbers, if the car was not entered in the firm's books as lent to me for a trial run they might have been summoned and perhaps fined. Of course, on the following day I ascertained that Messrs. Darracq had complied with all the requirements of the law. Still, this incident resulted in a sleepless night, during which I had time to reflect on the worries of my amateur calling as well as the need for insurance for cars likely to be used in traffic.

I took the car to Orpington, where I showed it to a medical motoring friend, and together we found some hills, which not only by their steep gradient, but by their unexpectedness and many twists, forced the vehicle to do its best, and in every way it was a very good best. With three up it climbed a hill of 1 in 6, and on this hill either set of brakes held it in both directions. Of course, what a prospective owner wants to know is whether the low cost makes its presence felt in any detrimental manner that might lead to wear of important parts, or breakdowns. From my test I am of opinion that cheapness had not been obtained at the price of quality, and that the car can be relied upon to give good results, and is well calculated to satisfy those needing a first-class machine that is essentially economical as regards initial and working costs; but, of course, as in the case of expensive cars, the parts must be kept lubricated and adjusted, especially the plain bearings. This is easily done, and anyone should be able very quickly to acquire the knowledge of how to do it. It is with a small car that most owners become experts in keeping it "tuned up," for whereas with, say a 50 or 60-h.p. the driver can afford to run it in an enfeebled condition, it is not so with a low-powered car, that naturally grumbles when it has to work under disadvantages; a 60-h.p. might go on two cylinders or with leaky valves, or two sooted plugs, a 10-h.p. would, anyway, not climb a hill when so handicapped. The car is turned out with a victoria hood and front screen, and with added side doors is comfortable and practically weather-proof.

*Gold Reflectors for Lamps.*

Messrs. Brown Brothers, Limited, have introduced a gold reflector for use in connexion with their Autoclipse lamps. This projects an agreeable warm-coloured light and in misty or foggy weather has certainly advantages over the ordinary silver variety. It can be fitted without much expense to old lamps.

*The Modern Methods of Setting Motor-Car Springs.*

The comfort of the occupant of a motor carriage depends chiefly on how the car is sprung, and this almost wholly consists on how the springs are set. In the earlier days each leaf of a spring was tempered and set so that before the load was received the distance between each component leaf was the same and corresponded to about the thickness of the most powerful leaf, each leaf, of course, only touching its neighbours at the ends. The longest plates have necessarily the most pull or "nip," and the up-to-date method is to have the distance between each plate graduated, commencing with a distance equivalent to the number of the plates mutiplied by the thickness of the top spring-plate and terminating with practically nothing at the bottom. Those who have old cars, which leave much to be desired in the matter of softness in riding, can by having their springs reset in this way by a capable coach-smith greatly improve the riding of their cars. I recently had the opportunity of a chat with a rather famous coach-smith who had by so doing completely eradicated the jog bumpiness of a friend's car. He complained rather bitterly of the hard lot of the spring, which because it seldom broke received no care. He advocated the taking down once a year of all carriage springs and of cleaning and greasing each plate; especially if they had been subjected to any undue stress, such as may occur through a severe jolt or collision with, say, a curb or bank, he thought that they should be reset, for the use of a dislocated spring may lead to a disaster.

*The Fitting of Speedometers.*

The question whether these useful accessories should be fitted by means of gears attached to the front wheel, or driven by a band off a split pulley attached to the Cardan shaft has been the subject of various letters which I have received from colleagues. Both methods are said to be satisfactory, but I certainly advise the former, although it is slightly noisy. When a belt is employed there is always the likelihood of slip and then inaccuracy.

*Should a Sprag be fitted?*

The answer, I think, is in the affirmative. Those who drive, I am sure, appreciate, when on a hill, being able to start the car without the worry of letting the clutch in just as the brake is taken off. In addition to being of use when after a stop on a hill the climb is continued, it is a sort of moral support to the driver, if new at the work, to know that it is there and down, and that, if in changing speeds he should miss his gears, there will be no backward movement. The old-fashioned variety hinged at its upper end to some part of the frame, with a keen chisel edge for the ground-striking extremity, has many advantages and is less likely to suffer derangement than the pawl and ratchet species.

## THE LONDON COUNTY COUNCIL AND MEDICAL AFFAIRS.

*Medical Attendance as an Emolument.*

THE General Purposes Committee having asked the Council to decide whether the emolument of "medical attendance" allowed to certain officers included medical or surgical attendance of an extraordinary kind—for example, a surgical operation, the following regulation was adopted. The words in italic were inserted in the General Purposes Committee's recommendation at the suggestion of the chairman of the Fire Brigade Committee:—

> Officials and employees who receive as an emolument medical attendance shall be entitled to receive advice and treatment by the medical officer under whose care they may be placed by the Council, but, except where *special treatment is necessitated by circumstances due to the nature of the occupation, or where* the Council considers that the particular circumstances of any case warrant special treatment, the Council will not provide special medical advice or any treatment other than that which can be given by such medical officer at the institution of the Council in which such official or employee is residing if in residence at an institution, or, if not in residence at an institution, then at the ordinary place of residence of such official or employee.

*Lunacy Statistics.*

The Asylums Committee has reported that the returns furnished by the clerks to the London boards of guardians and the information available in regard to London county asylums showed the number of lunatics under certificate on Jan. 1st, 1911, to be 26,845, as compared with 26,377 on Jan. 1st, 1910, an increase of 469. This, though greater than the increase recorded in 1910—namely, 84—might be contrasted with increases of 678 in 1909 and 403 in 1908. The average annual increase during the last 21 years of lunatics for whose accommodation the County Council was responsible was 479.

OLD-AGE PENSIONERS AND MEDICAL RELIEF.—At the last meeting of the Okehampton (Devon) board of guardians the clerk stated that every old age pensioner is not entitled to medical relief. He added that some of them had £400 in the bank. The relieving officer remarked that he should give medical relief to any old age pensioner, unless the applicant had sons who were in a position to bear the cost of medical attendance.

# THE LANCET RELIEF FUND.

THIS Fund, which came into operation on the 1st of February, 1889, has for its Almoners the President of the Royal College of Physicians of London (Sir THOMAS BARLOW, Bart., K.C.V.O., F.R.S., M.D. Lond.), the President of the Royal College of Surgeons of England (Mr. HENRY T. BUTLIN, D.C.L., LL.D.), the President of the General Medical Council (Sir DONALD MACALISTER, K.C.B., M.D. Cantab., LL.D., D.C.L., F.R.C.P. Lond.), and the EDITOR of THE LANCET (S. SQUIRE SPRIGGE, Esq., M.D. Cantab.), with Sir JOHN TWEEDY, LL.D., F.R.C.S., as Honorary Auditor.

***Almoners.***

FOR the guidance of those seeking assistance and of those desirous of recommending deserving cases, it may be useful to record that THE LANCET Relief Fund is sustained solely by the Proprietors of THE LANCET, who provide every January the sum of at least £300, which is administered free of cost, with the object of affording immediate pecuniary assistance to registered medical practitioners, or to their widows and orphans, in cases of distress and emergency, by the grant of money by way of loans free of interest, or gifts, as the circumstances of the various cases may require. In the case of widows and orphans, in order to come within the scope of the Fund, the death of the Husband or Father must have been of recent occurrence.

***Scope of the Fund.***

WHEN the Fund was inaugurated considerable misapprehension existed as to the precise objects for which it had been established, and, as a result, the majority of the earlier applications, being cases of *chronic* distress, and not coming, therefore, under the designation of *emergency*, could not be entertained. As the Almoners still receive applications for assistance for cases which are obviously of a *chronic* character, it is thought advisable to append a statement concerning cases of this nature which appeared in THE LANCET of Feb. 16th, 1889:—

***Chronic Cases Ineligible.***

"We are requested by the Almoners to state that, from the character of a number of the applications received, both personally and by letter, for relief, it is evident that in many cases the object for which this Fund has been established is not quite clearly understood; and if relief had been afforded in the cases of those who suffer from chronic distress the Fund would have been completely exhausted within the first few days of its existence. They would therefore be greatly obliged if those readers of THE LANCET who may be asked to endorse applications would carefully peruse the Application Form and explain the precise object of the Fund to those applicants whose cases do not seem to come within the scope of the purpose for which the Fund has been established, which is to afford prompt aid to registered medical practitioners, or to the widows or orphans of members of the profession, who, in consequence of the supervention of some unexpected emergency, which is not likely to recur, have pressing need of immediate and temporary pecuniary relief"—

And who, it may be again pointed out, are likely to be benefited permanently thereby.

## *Twenty-second Annual Report of the Almoners,*

*For the year ending December 31, 1910.*

IN presenting their Twenty-second Annual Report, the Almoners have to record that the balance in hand on Dec. 31st, 1909, was £332 1*s.* 2*d.*, to which on Jan. 5th, 1910, the Proprietors of THE LANCET added the sum of £300, making, with £2 10*s.* repaid on loans account, a total sum of £634 11*s.* 2*d.* available for grants during the year 1910.

The number of applications for assistance received by the Almoners during the year was 32, of which number 5 were declined by the Almoners after due consideration; 7 application forms were not returned—doubtless owing to the applicants realising that their cases were not of a nature qualifying them to receive assistance from the Fund; and 20 applicants were relieved by gifts or loans of money ranging from £2 10*s.* to £30. The relief of these 20 cases, a detailed list of which is given in the accompanying Statement of Accounts, involved the expenditure of the sum of £307 10*s.* The total amount voted by the Almoners since the commencement of the Fund is £6661 16*s.* 3*d.*

The Almoners have received many expressions of gratitude for the assistance which they have afforded to applicants—in some urgent cases the relief being given within a few hours of the application being received. An example of this promptitude was Case No. 842, which was considered and helped within two hours of the appeal being made to the Almoners. The timely help of the Fund has enabled more than one applicant to keep his practice together when pressing claims threatened to destroy his home and his means of livelihood; and the widow and the orphan have also been helped at the moment of their greatest need.

Sir Thomas Barlow, Bart., K.C.V.O., F.R.S., M.D. Lond., having succeeded Sir R. Douglas Powell, Bart., K.C.V.O., as President of the Royal College of Physicians of London in March last, thereupon became an Almoner of the Fund, and kindly consented to act as such. The Almoners desire to record their warm appreciation of the valuable services rendered to the Fund by Sir R. Douglas Powell during the period of his Almonership.

In conclusion, the Almoners would point out that they will

at all times be glad to have their attention called to any cases of genuine distress coming within the scope of the Fund, but they trust that those recommending cases or giving testimonials will first take steps to satisfy themselves of the *bona fides*, as well as of the suitability, of such cases before endorsing them. In the administration of such a Fund as this the Almoners are of necessity largely guided in their decisions by the testimonials accompanying the applications.

(Signed) THOMAS BARLOW. HENRY T. BUTLIN.

I find by the Banker's Book that the actual Balance on Jan 1st, 1910, to the credit of the Fund was £332 1*s.* 2*d.*, to which the sum of £300 was added by the Proprietors of THE LANCET on Jan. 5th, 1910. The balance at the Bank on Dec. 31st, 1910, was the sum of £338 17*s.* 0*d.*

I have examined this statement and compared it with the Vouchers and Bank Account, and find same correct.

Jan. 30, 1911. JOHN TWEEDY, Hon. Auditor.

EXHIBITION OF FRACTURES.—On the occasion of the Third Congress of the International Society of Surgery which is to be held at Brussels from Sept. 26th to 30th, 1911, it has been decided to hold an Exhibition of Fractures. Exhibits intended for the exhibition must reach the Secretary-General, 75, Avenue Louise, Brussels, from August 20th to 31st, who will return them at the end of the Congress. Specimens of every kind as well as documents relating to the study of fractures may be exhibited, notably (1) pathological specimens (various types of fractures and rare fractures); (2) radiographs, drawings, plaster casts, moulds, &c.; (3) apparatus for bloodless treatment (including apparatus for immobilisation, extension and ambulatory treatment); and (4) specimens and documents relative to osteosynthesis. Non-members approved by the international committee, for which approval the secretary-general will arrange, are invited also to take part. The sessions will be arranged so that exhibitors will be able to show their exhibits to the members of the society during the Congress, and subjects will be placed at the disposal of those who require them. Arrangements are being made for special reductions in the railway transport rates, as was the case with the Cancer Exhibition. Professor J. Lucas-Championnière is the President of the Third Congress, and Monsieur A. Depage is the secretary-general. Monsieur L. Mayer is the secretary of the Congress. Forms of application may be obtained on request.

# MEDICINE IN THE ENCYCLOPÆDIA BRITANNICA.

## I.—HISTORY OF ANATOMY.

IN our issue of Feb. 11th we referred in general terms to the new edition of the Encyclopædia Britannica and to the manner in which the special requirements of the medical profession were provided for. It is our intention in this and succeeding issues to consider more in detail the various articles in the Encyclopædia which deal with medical subjects. Medicine is dealt with as a whole in one article, which has not yet been issued, but the volumes contain a number of articles dealing with the causes, symptoms, and treatment of specific maladies. Among the contributors in the field of Medicine and Surgery are Sir Clifford Allbutt, Sir Lauder Brunton, Professor Robert Muir of Glasgow, Professor Sims Woodhead, Sir John Broadbent, Mr. Edmund Owen, and Mr. Stephen Paget, while Mr. F. G. Parsons has written the article on Anatomy which we deal with below, and has also planned the treatment of the subject throughout the volumes upon a comparative method.

Of Mr. Parsons's contribution we may say that the method of arrangement in this edition shows a marked contrast to that of earlier issues. The whole subject has been broken up from two articles into about 30, the anatomical descriptions of various parts of the body being found under such respective headings as arteries, heart, ear, eye, liver, skull, urinary system, &c. This arrangement has the advantage for the general reader of throwing all the information given about one organ or group of organs into one chapter—in effect a treatise on the biology of certain organs or functions. For a book of general reference this method is undoubtedly sound. The article on "anatomy" is therefore limited to an historical sketch and a few pages on the artistic aspect of the subject with which we are not concerned. The historical *résumé* forms a valuable monograph throwing important lights on the growth of scientific thought.

The history of anatomy as known to the Græco-Roman world is so far crystallised that it has not been deemed necessary to alter in any substantial details the article written by the late Dr. Craigie of Edinburgh for the ninth edition of the Encyclopædia. The number of extant authorities is small, and their writings have been submitted to minute criticism for at least three centuries. But the number of extant writers does not represent the sum total of workers in the anatomical field. Anatomy was a small excrescence on the art of healing, and that art was an hereditary priestcraft, handed on in families of distinction, attached to well-known temple shrines. Such was the family of the Hippocrates, for seven members of the race of the Heracleidæ bore this name in the Island of Cos, the "Father of Medicine" himself being Hippocrates the Second. We may reasonably look for future light on the origins of medicine in Crete when we remember that the Ionian population of the north-eastern Ægean was thrown out from the Mycenean cities of the Peloponnesus under the stress of the successive wars of the Dorian invasions. A curious hint is also afforded by the fact that the earliest anatomical treatise extant is an Egyptian papyrus of the sixteenth century B.C., at the probable zenith of the Minoan civilisation in Crete, just 200 years before the "destruction of the Palace" and the dismemberment of the great Cretan Empire.

It is undoubtedly wise not to attach too much importance to Hippocrates and his school as authorities on anatomy, in spite of the encomiums bestowed upon this branch of attainments by enthusiastic and learned admirers. His knowledge was necessarily defective owing to the impossibility of dissection, for the Greek feeling of respect for the dead offered a bar to its practice as complete as that presented ten centuries after by the Moslem religion. This estimate of Hippocrates' anatomical knowledge is confirmed in the short biographical article under his name from the pen of Sir John Batty Tuke. Hippocrates was one of the master minds of the world, a mind which was part of the huge intellectual output of post-Mycenean Greece, part of an output certainly never surpassed and possibly never equalled. Whatever his defects in anatomy may have been he remains a master at the bedside; Laennec admitted that Hippocrates had taught him "l'auscultation immédiate." If not the first to hold, he was the first to express, the conviction that diseases must be scientifically treated as subject to natural laws, however they may be regarded from the religious point of view. Nor was he anxious, as the author reminds us, to maintain the connexion between philosophy and medicine, for, according to Celsus, Hippocrates of Cos was "*primus quidem ex omnibus memoria dignus, ab studio sapientiæ disciplinam hanc separavit, vir et arte et facundia dignus*" (De Medicina). The article closes with a valuable note on the Hippocratic collection and the reasons for accepting some of the treatises as genuine and others as not so. There is no difficulty now in assigning a proper portion of the various Hippocratic writings to the great physician of Cos, for few writers have been exposed to such continuous criticism in the course of many centuries.

It is unnecessary to reclaim the title of the Father of Medicine. The treatise Περὶ ἀέρων, ὑδάτων, καὶ τόπων (Airs, Waters, and Places) is always the first treatise on public health. There is little to be said anew on such a hero of medicine, but the remark that Hippocrates advocates the use of the trephine with more boldness than the experience of later times has warranted, may suggest that the operation was still a survival of a practice of the Neolithic age. Among the followers and pupils of Hippocrates the most noted is his son-in-law, Polybius, to whom has been ascribed the whole of the book on the "Nature of the Child," and most of that "On Man." There is abundant anatomical matter in both, largely grotesque and inaccurate. The opinions of Syennesis of Cyprus and of Diogenes of Apollonia have been preserved for us briefly by Aristotle, and they indicate no more exact observation. With Aristotle himself anatomy, as a science based on direct observation, really began. The first three books of the "History of Animals" survive out of ten, and the four books of the "Parts of Animals." From them we learn that the errors of the three writers given above on the subject of the distribution of the blood-vessels were becoming recognised. Though Aristotle distinguished between arteries and veins, he confused the vena cava and the pulmonary artery.

The error, which died so hard and so late, that the arteries were air-vessels appears to have originated with Praxagoras of Cos, the last of the Asclepiadæ. The article before us seems to imply that Diocles of Carystus followed Aristotle in date; it was usually supposed that Diocles was a contemporary of Darius Hystaspes, who died in 485 B.C. The real study of human anatomy began in Alexandria during the reign of Ptolemy Soter and his successors. Herophilus and Erasistratus undoubtedly dissected and described the human body and were largely responsible for the high reputation of the Alexandrian medical schools. None of their writings have come down, but sufficient references have been made to them by Galen, Oribasius, and others for us to realise the value of their work. Erasistratus described and named the valves of the heart, the division, cavities, and membranes of the brain, and the folds of the jejunum. Both he and Herophilus described the brain, its shape, cavities, and convolutions, and the latter was the first anatomist to give his name to a part of the body. Mr. Parsons is perhaps wise in not assigning a date to Aretæus, as his exact historical position is not certain, though it was clearly in the first century A.D.

The scanty contributions of the Greek practitioners of the early Empire, who preceded Galen, have received all the attention they deserve. The work of Marinus and Rufus of Ephesus is chiefly conserved in Galen's writings, and with Galen's death in 200 A.D. classical anatomical knowledge ended. Soranus (the anatomist) and Oribasius, Miletius and Theophilus (chief medical officer to Heraclius), strove in vain to wear the mantle. The languid efforts of these compilers did little to improve the standard work carried out and personally recorded by Galen. Whatever value may be claimed for originality of clinical observation on the part of the Arabian physicians, their anatomical learning was borrowed from the Greeks, and Mondinus of Bologna, about 1315, laid the foundation stone of modern anatomy. But even in the Republican cities of Northern Italy the influence of the Church was too strong to permit such original workers as Gabriel de Zerbis of Verona or Achillini of Bologna, at the close of the fifteenth century, to gain a proper hearing in the schools. The infallibility of Galen was a tenet of faith upon which the powers of the Lateran insisted. Even such mental freedom as Sixtus V. afforded to science was a century away. We

recognise, with Mr. Parsons, the immense stimulus which the laborious compendium of Berenger afforded to students of anatomy, a stimulus assisted by the illustrations with which it was furnished. Poor as works of art, these plates were more useful to the student of the day than the artistic but useless drawings of Mondino, or the magnificent studies of Leonardo da Vinci or Albrecht Dürer.

Vesalius has always been claimed as the founder of modern anatomy, and no attempt is made in Mr. Parsons's article to depose him; but the admirable sketch of the work of Jacques Dubois, who was the original master of Vesalius in the science, shows how much the pupil owed. He was not the untaught heaven-born genius that some of his biographers have made him.

From the time of Vesalius to the time of Harvey the names of the greater anatomists seem like the names of the great navigators: they have been attached to bays and promontories, where instead of the titles of Hudson or Magellan we recognise Eustachi of San Severino, Fallopi of Pisa (pupil of Vesalius), Constantio Varoli (physician to Gregory XIII.), Fabricio, who first described the valves of veins, and his pupil, Casserius of Piacenza, with whom closed the illustrious line of Italian anatomists.

Proper space is given to the consideration of the question of provision by the State of subjects for dissection in authorised schools. The necessity of practical dissection was forced upon medical teachers in Great Britain by William Hunter about 1750, with the result that in 1793 there were 200 students studying regular anatomy, and by 1823 the numbers reached at least a thousand. The legalised supply of subjects was confined by a statute of Henry VIII. to the bodies of executed murderers, which happily for morals if not for science was limited even in those cruel days. The practice of "body-snatching" was the natural, if deplorable, outcome of an insufficient supply of subjects. The article under review gives an excellent summary of the difficulties which preceded the passage of the "Anatomy Act" of 1832. There was official opposition on the part of the Royal College of Surgeons of England, whose Fellows were jealous of any advantage which might possibly accrue to private teachers, who formed the majority of the anatomical schools. Other opposition came from parliamentarians like "Orator" Hunt, Michael Sadler, and Sir R. R. Vyvian (then Member for Bristol). Macaulay, in one of his most incisive speeches, illuminated by incidents of mediæval surgery, supported the Bill as one "which tends to the good of the people, and which tends especially to the good of the poor." It is to be regretted that in his final sentence on this subject Mr. Parsons shows that the same sentimentality which influenced Hunt and Sadler in 1832 is influencing boards of guardians to-day; for the Anatomy Act is not compulsory on such boards but only permissive.

Space forbids our entering on a consideration of that part of the article that deals with modern anatomy; suffice it to say that the ground is fully covered and the subject amply treated.

## RECORDS FROM MEDIÆVAL CORONERS' COURTS.

(FROM A CORRESPONDENT.)

IN THE LANCET of Dec. 17th last there were discussed some features of the Coroners' Law and Death Certification Amendment Bill, and an outline was given of the history of the office of coroner and the duties of that officer. It was pointed out that the coroner was closely connected with judicial matters, and that therefore in the beginning he might be expected to be a lawyer. To pursue the subject somewhat further, it may be added that the essential function of the early coroners was to guard the rights of the Crown. Criminals were sought out and deaths by violence and misadventure were inquired into, not so much because someone had died or had been killed, but because the death or the crime was a source of revenue to the Crown.

Coroners had a much wider field of inquiry in early days than they now have, for in addition to the duties mentioned in the article in question they were obliged to hear "appeals" or criminal accusations brought by one person against another. The final trial of the causes was reserved for hearing at the "eyre"—i.e., at the visit of the justices on circuit, the term "eyre" being derived from "in itinere." It was the coroner's duty to be present at the eyre; he held an important position, for he was the link between the itinerant justices and the local administration, and so between the Crown and the people. I propose to cite a few cases both from the records of coroner's courts and from those of the Crown pleas at the eyre, between 1200 and 1413, which I think will be found interesting both from a medical and from a historical point of view. Sundry expressions in the reports are somewhat puzzling unless the reader is aware of the procedure, so I have explained technicalities in the course of this article.

To begin with the inquest jury, the composition of this body varied in different places and at different dates, but about the thirteenth century it commonly consisted of representatives from four neighbouring townships—namely, from that in which the death occurred or in which the body was found, and from the three nearest townships. The number of jurymen varied, but was often, as it is now, 12. Persons declared guilty by the jury, those who were present when the sudden death occurred, and the finders of the dead body were all attached to appear at the eyre before the itinerant justices. The finder of the body was not, however, attached if the deceased had received the last rites of the church, because presumably he would then have been able to state who had attacked him. Thus we have the following entry in the coroners' rolls of Northamptonshire:—

> It happened at Little Houghton that Richard le Muleward was found dead on Saturday next after the feast of St. Dunstan in the sixth year of King Edward III. (May 23rd, 1332). An inquest was held before John de Tuwe the coroner on the aforesaid day and year by the oath of twelve jurors who say that Richard quarrelled with two men who killed him. There was no finder because he had the rites of the church.

That is to say, that no record of the finder of the body was kept because Richard had survived long enough to say who were his assailants and to receive the last rites.

The finder of a person feloniously slain had to raise the hue, and one method of doing this was for the finder to inform his four nearest neighbours, who then notified the bailiff of the hundred, who in turn sent for the coroner. At the inquest the chattels of the person indicted were appraised, and the property thus appraised was placed, as a rule, in the charge of the township in which the death occurred, to be accounted for at the next eyre. If the accused was found guilty his chattels were forfeit to the king. Sometimes the only chattel which a murderer possessed seems to have been the weapon with which he committed the crime. Thus on July 2nd, 1410, Richard Barber killed John Taylor with a sword at Weston in Staffordshire. He was found to have no goods or chattels, but the sword was valued at 2*s*., "for which the township of Weston is to account."

Murder was, as might be expected, a much simpler affair in the Middle Ages than nowadays. Poisoning was almost unknown, or possibly was never discovered as such, for the deaths by violence which are reported in the coroners' rolls are all due to injury by weapon and are often characterised by extreme brutality. On April 23rd, 1271, John Rede, Matilda his wife, and their two servants were sitting at supper in the town of Ravensden in Bedfordshire when certain felons and thieves came to the house. They hit John on the head with an axe and also stabbed him to the heart, so that he died immediately. Then they wounded Matilda in the head, nearly cut off her left hand, and, having heated a trivet, placed her upon it. Having bound the two servants, they despoiled the house and departed, leaving Matilda for dead. One of the servants unbound himself and raised the hue. At the inquest certain persons were ordered to be arrested, Matilda, despite her serious injuries, being able to attend and to give evidence. Our forefathers must have been a hardy race, for they had a wonderful power of recuperation. Witness the following case. At Barford in Bedfordshire, on Oct. 10th, 1271, John of Bretteville was walking with his wife Emma on the King's highway. To them appeared one Simon, who struck John with a sword of iron and steel on the top of his head, on the left side between the parting of the hair and the ear, making a wound 5 inches long, 3 inches wide, and extending down to the brain, so that 13 pieces of bone afterwards came out from the said wound. He also with the sword divided the tendons of the little finger of John's left hand and fractured the third finger of the same hand. Nor did his malice stop there, for he also struck John on the right side of his head with the flat of the sword, many blows which did not bleed

(*orbos ictus et multos*), so that the whole top of his head was excoriated and swelled up and he lost his hearing on the left side. Emma raised the hue, and on the following day she appeared at the county court before the coroner and there said that if her husband recovered he would sue in person at the next county court. Despite his severe injuries John appeared in person at the county court held on Nov. 30th, 1271. Simon was summoned at the following county court held on Dec. 21st, but did not appear. He was summoned again on Jan. 25th, March 21st, Feb. 27th, and finally on April 18th, 1272, John appearing every time. Simon, however, did not appear until the April court, but the record does not go on to say what happened to him.

Another interesting case is that of Henry Costentin, who in the parish of Eaton in Bedfordshire was on Thursday, August 11th, 1267, loading wheat into a cart. His feet slipped and he fell upon a pole of the cart so that the pole went into his fundament. He lived until the following Monday when he died at 6 A.M., having received the rite of the church. A verdict of death by misadventure was returned. The cart, the harness, and the wheat were valued at 6*d*., the horse at 2*s*. 6*d*.

In cases of death by misadventure the deodand was valued and confiscated for the crown. Deodanda was the legal term for any animal or inanimate objects by which a man came to his death. In accordance with its name it was supposed to be applied by the Crown to pious uses—i.e., to be distributed as alms. In an inquest held at Cowly, in Gloucestershire, on the body of a child aged 3 years, by name Robert Fox, a verdict was given that he fell into a pan of milk and was thus drowned. The inquest was held on Sept. 15th, 1396. The pan was valued at 6*d*. Several other inquests deal with the deaths of children from drowning in a well, and the circumstances of the following case are of interest from the point of compensation which would now probably be sought. William and John, both of Goldington in Bedfordshire, had a dispute on Sept. 26th, 1267, concerning some sheep, with the result that William received a wound on the head four inches long. He recovered from this and made it up with John. A little later William had an attack of ague and died, whereupon his wife raised the hue out of spite. The coroner, Simon Ruffus (Read), held an inquest at which Goldington and three other townships were represented. A verdict was returned that William did not die from the wound but from the ague. Nevertheless John was attached.

Inquests on deaths in prison were frequent and throw a sinister light on prison treatment. Thus at the inquest on Robert Rushton, who died in Northampton Castle on March 20th, 1323, 12 jurors say that he died from hunger, cold, and privation. John Swan, who died in the same prison on July 25th of the same year, was found to have died from hunger and the flux. Geoffrey of Steventon, a chaplain who died in the same prison on August 9th of the same year, was found to have died from hunger and thirst. The same was the case with Thomas Philip, Michael Smith, and Roger of Keston, who all died in the same prison.

I have referred above to a case in which 13 pieces of bone were extracted from the skull of a man who had been wounded in the head. But an even more remarkable case was heard at the Cornish eyre of 1201. Here Eadmer of Penwithen appealed Robert and two other men for that Robert wounded him in the head so that 28 pieces of bone were extracted. Robert attended the court and "defended the whole of it word by word." He was, however, sentenced to purge himself by ordeal of iron, and the two others were to be kept in custody until it should be seen how Robert should fare. Despite his injuries Eadmer was present in court. The action appears to have failed, for it is stated that Eadmer afterwards came and withdrew himself "et posuit se in misericordiam de j. marca"—i.e., he agreed to pay a fine of one mark. But that he should have recovered enough to prosecute after such a serious injury is worthy of note, and why he was fined is not clear.

The age was a rough one, but we find no records of such refinements of crime as are found in the criminal records of later days. There is one case noted at the Lincolnshire eyre of 1202, where Thomas appealed Alan for that Alan had taken him by force into his house "et eum tenuit dum uxor ejus (Alan's) abscidit ei unum testiculorum suorum et Radulfus Pilatus alterum"; in this mangled condition Thomas was carried by Alan into the road, where he raised the hue as soon as he could, and the king's serjeant was informed. This official came to Alan's house and "ibi invenit cultellum et testiculos in ciphulo quodam." But as a rule in quarrels or assaults, the simple dictum "when you see a head, hit it" was enough for our forefathers. A study of the volumes containing the pleas and cases upon which we have commented—namely Vols. I. and IX. of the Selden Society's publications—reveals the fact that nearly all the crime in the Middle Ages came under the head of crimes of violence; murder, buglary with or without assault, wounding, rape, and mutilation appear again and again. There are a few instances of petty theft and of cheating by false weights, but the elaborate swindles, the carefully thought-out and planned murder seem to have been unknown. They were reserved for an age in which education, despite all its benefits, may lead the criminally inclined down the road of wickedness no less than the ordinary person up the hill of improvement.

## THE HEALTH OF THE ARMY IN 1909.

### I.

WITH the publication of the fifty-first volume of the Army Medical Reports we notice that the title of the volume has been changed from "Army Medical Department Report" to "Report on the Health of the Army." A designation that has been in use for half a century cannot be dropped without some slight regret; but as there has been, strictly speaking, no "Army Medical Department" for many years past, the continuance of the old title was an anachronism. The new name is also more appropriate, since, although the work dealt with in the report is almost entirely that of the medical service, it derives its importance from the fact that it relates to the army as a whole. Continuing the practice of his predecessor, the Director-General summarises the chief points of interest in an introductory letter. The improvement in the health of the troops that has been noticeable since the conclusion of the war in South Africa is continued, and for 1909 a considerable decrease is noticeable in the four items of admissions to hospital, average number constantly sick, deaths, and numbers invalided. The following short table shows this clearly; the figures are ratios per 1000 :—

| — | Admissions. | Constantly sick. | Deaths. | Invalids. |
|---|---|---|---|---|
| 1889–1898 ... ... | 997·3 | 59·85 | 9·03 | 15·36 |
| 1904–1908 ... ... | 594·5 | 35·40 | 5·47 | 13·73 |
| 1909 ... ... ... | 504·8 | 28·86 | 4·10 | 8·65 |

The improvement, when the 1909 figures are compared with the averages of the preceding five years, is seen to be marked under each heading, and if the decennial ratios of the period immediately before the South African war be regarded, the results are in the highest degree satisfactory. The admissions to hospital and the numbers constantly sick are much below the quinquennial average, and are only about half the averages of ten years ago; the deaths are less than half and the invalids but slightly more than half these averages, and are considerably below the averages of the five years immediately preceding the year under review. The statistics for the years 1899 to 1903 are exceptional, owing to the South African war, and are not therefore properly comparable. As explained in last year's report, the decrease in admissions to hospital and in men constantly sick is due in a considerable degree to the introduction of the out-patient system of treatment in 1904, according to which slight cases of sickness are treated in barracks. The reduction in mortality and invaliding ratios is, however, quite independent of this change in medical administration; the figures for 1909 are appreciably lower than those for 1908, and by far the lowest that have yet been recorded.

The total force, amounting to 217,314 warrant and non-commissioned officers and men, may be divided into three groups from a medico-statistical point of view: the troops serving in the United Kingdom, who form rather more than one-half of this number (viz., 110,492); the Army of India (71,556); and the remainder serving throughout the rest of

the empire (35,266). What has been said above about the improvement in the army's health as a whole will be seen to be equally applicable to each of the three main groups into which it is geographically divided.

*Ratios per 1000.*

| — | Admissions. | Constantly sick. | Deaths. | Invalids. |
|---|---|---|---|---|
| | *United Kingdom.* | | | |
| 1889-1898 ... ... | 712·5 | 41·14 | 4·32 | 16·98 |
| 1904-1908 ... ... | 454·3 | 25·87 | 2·85 | 16·29 |
| 1909 ... ... ... | 378·4 | 21·72 | 2·92 | 10·51 |
| | *India.* | | | |
| 1889-1898 ... ... | 1464·7 | 89·61 | 16·43 | 14·78 |
| 1904-1908 ... ... | 839·1 | 50·68 | 10·07 | 11·24 |
| 1909 ... ... ... | 716·9 | 40·26 | 6·37 | 6·35 |
| | *Colonies.* | | | |
| 1889-1898 ... ... | 869·6 | 54·37 | 8·44 | 11·24 |
| 1909 ... ... ... | 461·6 | 28·10 | 3·77 | 7·37 |

The chief causes combining to bring about this improvement in the army's health have, no doubt, been the same as were alluded to in the previous year's report—viz., changes in medical administration; improved methods of treatment in hospital, especially the great increase in operative surgical measures during recent years; improvements in sanitation; and the employment of medical officers as medical inspectors of recruits, which has led to greater care in their selection.

*Recruiting.*

The number of recruits medically examined has been 50,298; this is a considerable decrease on 1908, when 61,278 were inspected, and is a much smaller number than in any previous year; no reason is suggested for this decrease. The standards have been raised during the year; for infantry of the line the minimum height has been increased from 5 feet 3 inches to 5 feet 4 inches, and the chest measurement from 33½ inches to 35 inches, a range of expansion of 2 inches being required. For garrison artillery the height has been raised 1 inch to 5 feet 8 inches. For departmental corps the standards remain the same, a height of 5 feet 3 inches; chest measurement 33½ inches, with an expansion range of 2 inches. The minimum age is, as before, 18 years, a few special reservists being enlisted at 17. The standard of examination tends to become more uniform year by year, partly owing to the more careful instruction of junior medical officers on joining, and partly owing to the frequent inspections of recruits at depôts by the specially appointed medical inspectors. It is noted that the only question on which there is now any considerable difference of opinion is that of the state of the recruit's teeth in reference to his general physique; facilities for dental treatment are being increased, and the problem will become simplified.

The Director-General considers that the quality of the recruits was, on the whole, satisfactory, and that they would be likely to develop into a good stamp of soldier, with few exceptions, but that they must not be expected to do the work of a seasoned soldier for two or three years at least. The ratio of rejections was 299·04 per 1000, being somewhat higher than in the two years preceding, but lower than the ten-year average of 307·97 (1899–1908). The chief causes of rejection have been, as usual, defective chest measurement (58·27 per 1000), loss and decay of many teeth (54·87), heart disease (33·06), and defective vision (18·35). The rejections for chest measurement, as well as for height, have been in greater proportion this year on account of the raising of the standards. The condition of the teeth of recruits is now receiving attention, and an increased expenditure has been sanctioned for dental treatment; but real improvement is only to be looked for from education of the child in the care of its teeth at an early age. The work that is being done by education authorities throughout the country in this direction must exert a beneficial influence in the near future; but as far as recruiting is concerned, it will be several years before the good effects of preventive dental treatment in schools reach the army. There is no doubt that, as stated in the report, a certain proportion of recruits are able to get good value for the food ingested, and possess an excellent physique, in spite of a low dental efficiency; but, on the other hand, it is quite possible that they would be in even better condition physically if their teeth were in a sound condition; and there are certainly very large numbers of young adults of the age and class in life from which recruits are drawn for whom preventive dental treatment would make all the difference in the world in regard to their physical fitness.

Heart affections have caused a slightly larger number of rejections on first examination (33·06), but fewer within three months of enlistment (1·15). Many of these later rejections are due to disordered action of the heart, which is said to be aggravated, if not induced, by cigarette smoking. It is observed that "there is a possibility, if not an actual probability, that future years may not witness any further marked diminution in these affections as a whole, but that the disease itself and the cause will be changed to another in the same category." This is a cryptic saying which we do not understand. We should have thought, however, that it would not be impossible for military officers to exercise some such control over the young soldiers as would prevent them from injuring their constitutions by excessive smoking. The rejections for defective vision continue to show a diminution, the ratio per 1000 examined being now only 18·35; in the period 1899–1908 the analogous figure was as high as 34·02; the reason is that the method of testing is now by means of Snellen's test types, instead of the test dots formerly in use; the standard required, one quarter of normal vision in each eye, or normal vision in one, and one-sixth in the other eye, cannot be considered too severe.

The determination of the recruit's age in doubtful cases is still "an unsolved problem to the medical examiner of recruits." The main defect of our recruits has always been want of maturity, and in the past year there has been no appreciable improvement in this respect; the quality of the recruits has been, on the whole, satisfactory, and they should develop into a good type of soldier; but it must not be expected that they can "do the work of a seasoned soldier for at least two or three years." We do not think this need cause anxiety; during these two or three years they are being well fed, clothed, and trained; the State gets the benefit of this as well as the individuals. But it must be remembered (though sometimes forgotten by commanding officers) that during these first two or three years they are not capable of doing the work of fully grown men; and it is to be regretted that their services should be lost by discharge so soon after they have reached maturity in bodily development and skill in military training.

Of the total number of recruits finally approved during 1909—viz., 34,731—after deducting those under 18 years of age (3491), the average age was $19\frac{5}{12}$; the height was 66·5 inches; the minimum and maximum chest measurements were 33·6 and 36 inches; the range of expansion, 2·6 inches; and the weight, 130·1 pounds. All of these ratios are higher than the 10-year averages, 1899–1908, with the exception of the age, which in the decennium had averaged 20 years. These figures must be allowed to be satisfactory. The system of physical training introduced at the end of 1906 has now become general throughout the army; it is gradually progressive in easy stages, and is designed to develop the body generally, not mainly to increase muscular development, as in the former system of training. Great care is taken in the selection of the instructors and in medical supervision of the gymnastic courses. There is now a fairly general agreement among medical inspectors of recruits that of the lads discharged medically unfit within three months of enlistment it is cigarette-smoking, and not physical training, that causes their disability.

*Invaliding.*

The invaliding ratio, which was 13·26 per 1000 in 1892, rose to 29 in 1901; for the five years 1904–08 it averaged 13·73; in 1908 it was only 10·32; and in 1909 it fell to 8·65, a much lower figure than has ever before been reported. The chief causes are tuberculous diseases (1·46), nervous diseases (0·91), and valvular heart disease (0·89 per 1000). The most marked reductions have taken place in the group of digestive diseases and in syphilis. Valvular heart disease also, though one of the chief reasons for invaliding, caused only 0·89 compared with 1·57 per 1000 in the preceding

quinquennium; and disordered action of the heart only 0·29 in comparison with 0·56.

Amongst the troops serving at home those quartered in the London District always show more sickness than any others. The ratios for the whole of the troops at home have been stated above. In the London area the admissions were 677, the number constantly sick 40·3, and the invaliding 17·5 per 1000; in the Western Command, on the other hand, these ratios were only 277, 12·9, and 10·5 respectively. Comparing the different arms of the service, the Household Cavalry have the highest admission-rate (654) and the Foot Guards the highest number constantly sick (38·6). The respective figures for Infantry of the Line are 407 admissions and 23·8 constantly sick per 1000. The Foot Guards, however, show a great improvement compared with the corresponding ratios for the past five years, which were 731 admissions and 52·6 constantly sick per 1000; while the Household Cavalry are rather worse this year than their quinquennial average (650 admissions and 25·2 constantly sick per 1000). From a table that is furnished in the report, comparing the death-rates of soldiers with the rates for civilian males, aged 15 to 35, from certain diseases, the advantage appears to be generally on the side of the military. Thus, the enteric fever death-rate was 72 per 1,000,000 compared with 143 for civilians; for tubercle of lung, 273 compared with 1438, and for other tuberculous diseases 40, compared with 211. Alcoholism caused only 24 deaths per 1,000,000 in soldiers, compared with 31 in civilians. Allowance must be made for invaliding, which would discount the apparent advantage in tuberculous diseases, but would not affect enteric fever or alcoholism; these diseases are therefore less fatal in the soldier than in the civilian of similar age.

The most fatal diseases were pneumonia (0·41 death per 1000), tubercle of the lung (0·27), and valvular heart disease (0·18). The diseases causing most sickness were gonorrhœa, syphilis, and soft chancre, which together caused a constantly sick rate of 6·20 out of the total 21·72 per 1000; this, however, is an improvement on the average for 1904–08, which was 7·90. The chief diseases causing invaliding were tubercle (1·74 per 1000), diseases of the nervous system (1·70), and heart disease (1·41); of these the tuberculous group show a slight increase on the quinquennial average (1·69). In last year's report attention was drawn to the need of some coöperation between the military authorities and municipal bodies or charitable institutions possessing open-air sanatoriums, which would offer to men on their discharge from the army some prospect of that after-care and attention which is so necessary if they are to recover their places in civil life as able-bodied citizens. Unfortunately, it has not been found possible, up to the present, to devise any general scheme to this end; but for the Aldershot Command four beds are reserved in the Frimley Sanatorium for discharged soldiers, whose condition gives hope for cure or improvement, on payment of 10*s.* a week, half of which is contributed by the Soldiers and Sailors' Help Society, and half by the regiment. We think, however, that the whole cost of this sanatorium treatment, after discharge from the army, should not fall on the private (or voluntary) charitable resources of the military, whether through regimental agency or the Help Society. Most of the men invalided would become chargeable to the public sooner or later after their discharge; and it seems only fair that the public generally—that is, the civil authorities—should bear some of the burden in the way previously suggested, namely, by allotting accommodation to ex-soldiers in sanatoriums, preferably in the territorial area to which they belong. Diseases of the heart and circulatory system caused nearly as many deaths (0·32 per 1000) as the quinquennial average (0·36); but led to much less invaliding, 1·61 per 1000 compared with 3·09. This indicates the success of the measures now being taken to eliminate heart-strain, as far as possible, from the exercises of the soldier; and especially that the physical training, as now carried on, is in agreement with sound physiological teaching.

Venereal diseases caused 28·6 per cent. of the total amount of sickness; in the decennium, 1891–1900, they caused 31 per cent. The improvement appears to be very slight, but it must be remembered that the *total* sick ratio in that period was 39·52, while in 1909 it was 21·72 per 1000; there is, therefore, really a very considerable reduction in the amount of these diseases. In 1901 there were 847 men constantly sick in hospital with venereal disease, out of a force of 100,811; in 1909 there were 685 men similarly *hors de combat* out of a force of 110,492. There is no doubt that the spread of temperance among soldiers is the chief, though not the only, reason for this improvement. Great variation is seen, as always, in the incidence of these affections. In the London District they caused 160 admissions per 1000, at Aldershot 48, on manœuvres 22. The bad pre-eminence of the London District (that is, the Household Troops) is less marked than in recent years, for in 1907 there were as many as 208 admissions per 1000 for venereal disease, but it is unsatisfactory. None of the specific infectious diseases were prevalent in 1909 except influenza, which caused 18·4 admissions per 1000, but it was not of a severe type.

# PLAGUE IN RUSSIA AND IN THE NEAR AND FAR EAST.

(FROM THE BRITISH DELEGATE TO THE CONSTANTINOPLE BOARD OF HEALTH.)

### *Plague in Odessa.*

THE following has been the course of the plague outbreak in Odessa since the date of my last letter on this subject (published in THE LANCET of Jan. 7th, p. 59). In the week ending Nov. 5th 4 cases with 1 death occurred in the town, none in the district round. The totals had then reached 140 cases and 43 deaths. Apparently no further cases occurred in November or December, but on Jan. 11th (Dec. 29th, Old Style) 2 fresh cases were reported. Since then Odessa and neighbourhood seem to have been free from plague. It is noted that some time in November, out of 522 rats caught in the town and examined bacteriologically one was found to be plague-infected.

### *Plague in the Kirghiz Steppes.*

A large number of plague centres seem to have formed in the past few months in various parts of the Kirghiz steppes of the Astrakhan government. On the island of Kuklen, in the second arrondissement of the first *okrug* (circuit) of these steppes 6 cases of plague, all fatal, occurred between Oct. 13th and 30th (Old Style). There were no further cases here in the following week. In the Djalpak settlement (*urotchishtché*), situated in the fourth arrondissement of the second *okrug*, 15 cases of the disease with 11 deaths were recorded between Nov. 1st and 12th. In the Djalpak-Tchagyl settlement (probably the same as the one just named) 20 cases with 19 deaths had occurred by Nov. 15th. One further case was reported here on the 22nd. In the Naurzali-Tchagyl settlement, situated in the second arrondissement of the first *okrug*, 4 deaths from pneumonic plague were reported on Nov. 18th. Other reports put the figures for this place at 5 cases and 5 deaths between Nov. 10th and 17th, followed by 1 case on the 21st, which died on the 25th. In the Mueren settlement 1 fatal case occurred on Nov. 4th, and in that of Abil-Ishken (twelfth arrondissement of first *okrug*) single cases (all fatal) were seen on Nov. 9th, 11th, 14th, and 16th. In the Tchushak settlement (second *okrug*, third arrondissement), 1 person fell ill on the 23rd and died on Nov. 24th. In the Biskyz settlement (on the frontier of the second *okrug*) 10 cases of plague with 9 deaths occurred between Nov. 17th and 30th, and 2 further cases were recorded here, at a date not stated. Some time in November the disease appeared in the Boman settlement (second *okrug*, second arrondissement); at that of Kara-Syr (fifteenth arrondissement of first *okrug*), where 7 cases and 6 deaths occurred; and in that of Musrep-Tchagyl, in the sixth arrondissement of the Sarak district, where 5 cases of pneumonic plague, all fatal, were recorded. In the Kolden settlement, in the second arrondissement of the Narynsk district, 4 suspected cases with 1 death occurred on or about Dec. 12th; 1 suspected and fatal case was seen in the Kolybai settlement (sixth arrondissement of the Kamysh-Samara district) at a date not named; and 5 cases with 1 death occurred there between Dec. 10th and 13th, followed by another case on the 16th. In the Iliman settlement (third arrondissement of the second *okrug*) 1 fatal case occurred on Dec. 19th. In the Kosai settlement (second arrondissement of the second *okrug*) 5 cases and 2 deaths had occurred in the first half of December, followed

by 13 cases and 6 deaths between Dec. 17th and 25th; 2 further deaths occurred here on the 26th.

In the settlement of Ak-Tchagyl, in the district of Kamysh-Samara, 9 cases of plague with 2 deaths were recorded between Dec. 22nd and 27th; 2 further deaths occurred here on the 28th, and 4 more between that date and Jan. 3rd. At a place called Sheshekti, in the second *okrug* of the Primorsk (or Maritime) district, 2 fatal cases occurred on Dec. 16th. Finally, at Bezo-Kyzo, in the first *okrug* of the Primorsk district, 1 death from plague occurred on Dec. 22nd, and 2 cases with 1 death on the 30th; these last occurred in members of a family under cordon.

From the above rapid summary it will be seen that plague has been present in at least 17 different places in the Kirghiz steppes of the Astrakhan government, and that these places are situated in many different parts of those regions. All the dates mentioned in this paragraph are according to the Old Style.

*Plague in Transbaikalia and Manchuria.*

From telegrams published in the English papers it would seem that not only has a severe epidemic of plague established itself in Transbaikalia and in Manchuria, but that the disease in its worst form—the pneumonic—has spread thence to some of the most densely inhabited portions of China, where it has already caused a high mortality. No official news has been received here respecting the epidemic in China, but the following information has become available, from Russian official sources, concerning the outbreaks in Transbaikalia and Manchuria.

In the Chinese population in the settlement round the station of Manchuria, on the China-Oriental Railway, from the beginning of October down to Nov. 3rd (Old Style), 212 cases of pneumonic plague, 207 of which were fatal, occurred. At the Tchalainor mines 31 cases, all fatal, were recorded among Chinese labourers between Oct. 20th and Nov. 1st. Single cases had then occurred at the stations of Tchalantun, Bukheidé, Khailar, and Harbin. At the Tarbagatai mines, in Transbaikalia, 2 deaths had occurred; at Verkhneudinsk, 1 death; at Petrovsk, 4 cases and 1 death (these included the cases of Dr. Noniava and 2 sanitary employees). At this time an order was issued forbidding Chinese labourers to enter the Primorskaia (or Maritime) Province from Manchuria until the end of the epidemic, and other measures were taken. In Transbaikalia the outbreak as a whole does not seem to have been a very severe one. From Sept. 15th to Nov. 9th the totals for the province were put at 28 cases with 25 deaths. In November an increasing number of corpses of Chinese found dead in the streets was reported from Harbin; and towards the end of the month the disease was said to be causing an increasing mortality at Fu-Chia-tien, and in towns and villages situated on the trade roads between Tsitsikar and Blagoviésctchensk. In mid-December some 30 cases were daily occurring in the streets and houses of Fu-Chia-tien.

Meanwhile the disease had been causing a high mortality in the region of exploitation of the Manchuria-Oriental Railway. Between Oct. 13th and Nov. 21st 468 cases with 466 deaths had been registered here among Chinese, and 11 cases with 10 deaths among Russians. (The enormously high rate of mortality will be noticed.) Apparently the epidemic died down about this time, as the totals down to Dec. 10th were placed at only 491 cases and 488 deaths among the Chinese, and (as before) 11 cases and 10 deaths among Russians. But by some date not clearly stated, towards the end of December, these same totals were reckoned at 588 cases with 578 deaths for the Chinese and 14 cases with 13 deaths for the Russian population. At the moment of writing a still later official bulletin has come to hand, and this states that in the region above defined 154 cases of plague with 152 deaths occurred between Jan. 1st and 6th; that of these 136 cases with 135 deaths were recorded in the town of Harbin, and the rest in six other stations on the railway, and that the total numbers since Oct. 13th down to Jan. 6th had been 831 cases with 821 deaths among the Chinese, and 25 cases with 24 deaths among Europeans. Professor Zabolotny, the well-known Russian authority on plague, and Dr. Predtéchenski have been sent to the infected districts in Manchuria, with powers to organise measures for the control of what is evidently a serious epidemic of plague, apparently in its most fatal form. In this paragraph, also, all the dates mentioned are according to the Old Style.

*Plague in Batoum and Baku.*

A single suspected case was reported from Batoum on Jan. 24th. On Dec. 2nd (15th) a case also occurred in Baku; the patient, a young girl, died, and there was bacteriological proof that the disease was plague.

*Plague in Jeddah.*

The seasonal revival of plague in Jeddah has again to be reported. The first case was seen on Dec. 22nd; it was only seen after death. The patient, a native porter, had died after a six days' illness. No other case was reported until Jan. 15th, and a few further cases have occurred since, including those of two Indian pilgrims isolated on Jan. 22nd.

Constantinople, Jan. 28th.

## MEDICINE AND THE LAW.

*Medical Treatment after School Inspection: the Legal Position of Parents.*

A CORRESPONDENT calls attention to a prosecution successfully instituted at Bridgwater in December of last year against the father of a little girl attending a local elementary school in the neighbourhood. The school medical officer had found the child's sight to be very defective, and he deposed in the witness box that neglect of treatment would prove detrimental to her physical ability in several ways. In consequence of the report made by the school medical officer the defendant, described as a "groom-gardener," received notice requesting him to send his child to Bridgwater to be examined by the county oculist, the provision of spectacles being apparently the limit of the treatment contemplated. The parents, however, took no steps in the matter, and the father, who pleaded guilty before the magistrates, expressed himself as being personally quite "indifferent." He treated it as the business of his wife to which she should attend, and stated that he could not make her take the child to the oculist. The bench inflicted a fine of £2 with costs, of which none will disapprove, but the correspondent referred to suggests that the success of the prosecution may have been due to the openly expressed indifference of the father to his child's welfare, and to the neglect of both parents to take any steps whatever to remedy a source of suffering to their child, to which their notice had been called and for which a remedy was offered to them. He asks for the expression of an opinion as to what would happen in a parallel case where the parents refused to allow a child to submit to a surgical operation. Our correspondent, no doubt, has in his mind the not infrequent case of the injured workman who claims compensation for an accidental injury, the effects of which might be removed or mitigated by a surgical operation which he declines to undergo. To quote from his letter; he writes, "It would be of great interest to those, like myself, concerned in school management, to know whether, had the condition of the child necessitated operation for its adequate treatment, for instance, had it been deaf owing to adenoid vegetations, it is likely that the parent could have been successfully prosecuted under the same section[1] for failing to take steps to have such operation carried out. My own opinion is that unfortunately such a prosecution would have failed, and that in the case reported it was the admitted indifference of the parent that enabled the prosecution to be successful."

We do not recall any quite similar case brought before the High Court on appeal in which the law relating to the subject has been discussed, and definite principles laid down for the guidance of courts of petty sessions and other tribunals, but possibly other readers may have had experience of prosecutions instituted successfully or unsuccessfully without any further question being raised. In our view all such prosecutions must depend upon the facts of the individual case brought forward and upon the evidence adduced as to the necessity for the operation for the relief of suffering in the child, the certainty of its fulfilling its object, the absence of danger to the patient, the extent to which inconvenience or

[1] Children Act, 1908, Section 12.

suffering is likely to continue or increase in the absence of operative treatment, and the amount of facility at the command of the parents for obtaining such treatment. The facts of cases of the kind indicated are likely to differ widely, and the evidence adduced by the prosecution to be of varying weight. The opinions, possibly preconceived, of magistrates also may vary considerably, and to some extent must be taken into account. If we consider, for instance, the suggested example of the removal of adenoid growths, this operation may have been successfully performed in the case of a child of a magistrate, who may thus himself have been enabled to estimate the relatively small amount of pain and inconvenience entailed and the benefit likely to accrue. Naturally, his attitude towards a parent refusing to secure the performance of a similar operation upon his child would be affected, and rightly so, by his own experience. The magistrates on occasions of this kind are asked to find as a fact that the child or young person concerned has been "neglected in a manner likely to cause such child or young person unnecessary suffering or injury to his health," and a finding that he has been so neglected can only be upset by a divisional court upon the ground that there was not sufficient evidence upon which to found it. The judges are not asked on appeal to say whether or not they would have come to the same conclusion upon the evidence, but whether there is evidence upon which it might reasonably be arrived at.

The exact words of the 12th section of the Children Act are very wide, and the application of them should present little difficulty where there is proof of avoidable suffering existing or being threatened. They are, so far as they are material to the present case, words relating to other forms of cruelty being omitted: "(1) If any person over the age of 16 years who has the custody, charge, or care of any child or young person wilfully neglects such child or young person, or procures such child or young person to be neglected, in a manner likely to cause such child or young person unnecessary suffering or injury to his health (including injury to or loss of sight, or hearing, or limb, or organ of the body, and any mental derangement), that person shall be guilty of a misdemeanour, and shall be liable (*a*) on conviction on indictment, to a fine not exceeding one hundred pounds, or alternatively, or in default of payment of such fine, or in addition thereto, to imprisonment, with or without hard labour, for any term not exceeding two years; and (*b*) on summary conviction, to a fine not exceeding twenty-five pounds, or alternatively, or in default of payment of such fine, or in addition thereto, to imprisonment, with or without hard labour, for any term not exceeding six months; and for the purposes of this section a parent or other person legally liable to maintain a child or young person shall be deemed to have neglected him in a manner likely to cause injury to his health if he fails to provide adequate medical aid for the child or young person, or if being unable otherwise to provide such medical aid he fails to take steps to procure the same to be provided under the Acts relating to the relief of the poor. (2) A person may be convicted of an offence under this section, notwithstanding that actual suffering or injury to health, or the likelihood of such suffering or injury to health was obviated by the action of another person. (3) A person may be convicted of an offence under this section, notwithstanding the death of the child or young person in respect of whom the offence is committed." It will be observed that special mention is made of neglect likely to affect the sight or hearing of the child, so that the actual case of the visit to the oculist, and the suggested one with regard to adenoid growths and their removal are both within the section. Note also that it is obligatory upon the parent to take steps to provide medical aid or to procure it under the Poor-law. He is not merely to accept it when offered or brought to his door. The neglect, however, must be "wilful."

*Substantial Fines for Watering Milk.*

The defences raised by defendants in cases where the alleged adulteration of food is the subject of the prosecution against them sometimes almost provoke a smile. At the Stratford police court recently a milk-seller was summoned on two informations respectively charging him with selling milk containing 19 and 35 per cent. of added water. The suggestion made on his behalf was that the lad, 13 years of age, who was in charge of his milk cart, was so confused by the appearance of the inspector that on being asked for samples he forgot to mention that the milk was sold as skimmed milk. The possible omission to give this information in the case of customers purchasing for their own consumption appears to have been taken into consideration by the bench in imposing fines of £5 and £10, the magistrate saying that the case was the worst he had met with in an experience of 23 years.

# VITAL STATISTICS.

## HEALTH OF ENGLISH TOWNS.

IN 77 of the largest English towns 8035 births and 5673 deaths were registered during the week ending Feb. 18th. The annual rate of mortality in these towns, which had been equal to 16·1, 16·0, and 17·6 per 1000 in the three preceding weeks, declined to 17·2 in the week under notice. During the first seven weeks of the current quarter the recorded death-rate in these towns averaged 16·2 per 1000, and corresponded to the recorded rate in London during the same period. The annual death-rates in the 77 towns during last week ranged from 8·4 in Smethwick, 9·8 in Handsworth (Staffs), 9 9 in East Ham, and 10·1 in King's Norton and in Tynemouth, to 23·2 in Plymouth, 23·4 in Oldham, 24·1 in Swansea, and 26·1 in St. Helens. The 5673 deaths from all causes in the 77 towns showed a decline of 110 from the number returned in the previous week, and included 621 which were referred to the principal epidemic diseases, against 461, 477, and 525 in the three preceding weeks; of these 621 deaths, 333 resulted from measles, 132 from whooping-cough, 64 (of infants under two years of age) from diarrhœa, 55 from diphtheria, 21 from scarlet fever, and 16 from enteric fever, but not one from small-pox. The fatal cases of measles, which had steadily increased during the first six weeks of the current year from 160 to 249, further rose last week to 333, and caused the highest annual rates of 2·6 in Bury, 2·7 in Gateshead, 2·9 in Rochdale, 3·0 in Devonport, 4·6 in Rotherham, 4·8 in St. Helens and in Rhondda, and 7·4 in Sheffield. The deaths from whooping-cough, which had increased from 85 to 123 in the four preceding weeks, further rose last week to 132; the highest rates from this disease were 2·4 in Willesden, 2·5 in Norwich, and 4·3 in Reading. The deaths of infants under two years of age attributed to diarrhœa, which had been 47 and 55 in the two preceding weeks, rose again last week to 64, and caused a death-rate of 1·4 in Burnley. The 55 fatal cases of diphtheria showed a decline of 3 from the number returned in the previous week, and included 17 in London and its suburban districts, 6 in Liverpool, 5 in Leeds, and 3 in Northampton. The 21 fatal cases of scarlet fever were equal to the number returned in each of the two preceding weeks; 5 deaths occurred in Liverpool and 2 in Manchester. The 16 deaths referred to enteric fever showed a decline of 3 from the number in the previous week, and included 3 fatal cases in Stoke-on-Trent, and 2 each in London, Liverpool, and Hull. The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospital, which had steadily declined in the 14 preceding weeks from 1882 to 1257, had increased to 1276 on Saturday last; 166 new cases of this disease were admitted to these hospitals during last week, against 129, 130, and 147 in the three preceding weeks. These hospitals also contained on Saturday last 865 cases of diphtheria, 469 of measles, 183 of whooping-cough, and 48 of enteric fever. The 1613 deaths from all causes in London last week (showing a decline of 16 from the number in the previous week) included 421 which were referred to diseases of the respiratory system, against 374, 365, and 404 in the three preceding weeks. In the 77 towns 163 deaths resulted from different forms of violence, against 178 and 187 in the two preceding weeks, and 438 inquest cases were registered. The causes of 50, or 0·9 per cent., of the deaths registered during the week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Manchester, Leeds, Bristol, West Ham, Newcastle-on-Tyne, Nottingham, Leicester, Salford, and in 47 smaller towns; the 50 uncertified causes of death in the 77

towns last week included 12 in Birmingham, 10 in Liverpool, 3 in St. Helens, and 3 in South Shields.

### HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns 843 births and 698 deaths were registered during the week ending Feb. 11th. The annual rate of mortality in these towns, which had steadily increased from 14·8 to 19 8 in the four preceding weeks, declined to 19·0 in the week under notice. During the first seven weeks of the current quarter the death-rate in these towns averaged 16·9 per 1000, and was 0·7 above the mean rate during the same period in the 77 English towns. The annual death-rates last week in the eight Scotch towns ranged from 13·2 and 13·7 in Aberdeen and Edinburgh to 21·1 in Greenock and 25·3 in Dundee. The 698 deaths from all causes in the eight towns last week showed a decrease of 30 from the number returned in the previous week, and included 68 which were referred to the principal epidemic diseases, against 46, 63, and 69 in the three previous weeks; these 68 deaths were equal to an annual rate of 1·9 per 1000, the highest epidemic rates being 2·2 in Glasgow and 8·9 in Leith. Of these 68 deaths from the principal epidemic diseases, 45 resulted from whooping-cough, 9 from diarrhœa, 7 from diphtheria, 4 from measles, 2 from enteric fever, and 1 from scarlet fever, but not one from small-pox. The fatal cases of whooping-cough, which had been 14, 22, and 33 in the three previous weeks, further rose to 45 last week, of which 26 occurred in Glasgow, 13 in Leith, and 3 in Dundee. The 9 deaths attributed to diarrhœa showed a decline upon recent weekly numbers, and included 6 of infants under two years of age. The deaths from diphtheria, which had been 8, 9, and 11 in the three preceding weeks, declined last week to 7, of which 4 deaths occurred in Glasgow. Of the 4 deaths from measles, 2 were recorded in Edinburgh. The 2 fatal cases of enteric fever were registered in Glasgow, and that of scarlet fever in Greenock. The deaths in the eight towns referred to diseases of the respiratory system, which had been 117, 138, and 161 in the three previous weeks, further rose last week to 181, and were 46 above the number returned in the corresponding week of last year. The deaths resulting from different forms of violence, which had been 27 and 28 in the two preceding weeks, declined to 22 last week. Of the 698 deaths from all causes in the eight towns last week, 201, or 29 per cent., occurred in public institutions. The causes of 19, or 2·7 per cent., of the total deaths were not certified or not stated; in the 77 towns last week the proportion of uncertified causes of death did not exceed 0·9 per cent.

### HEALTH OF IRISH TOWNS.

In the 22 town districts of Ireland, having an estimated population of 1,163,596 persons, 600 births and 507 deaths were registered during the week ending Feb. 18th. The annual rate of mortality in these towns, which had been 19·6 and 24·1 per 1000 in the two preceding weeks, declined to 22·7 in the week under notice. During the first seven weeks of the current quarter the annual death-rate in these towns averaged 20·9 per 1000, whereas in the 77 largest English towns during the same period the death-rate did not exceed 16·2, and in the eight principal Scotch towns it was equal to 16·9 per 1000. The annual death-rate last week was equal to 25·5 in Dublin, 19·5 in Belfast, 25·3 in Cork, 29·7 in Londonderry, 10·9 in Limerick, and 23·4 in Waterford; in the 16 smallest of the Irish town districts the annual death-rate last week averaged 23·8 per 1000. The 507 deaths from all causes in the 22 towns last week showed a decrease of 31 on the number returned in the previous week, and included 29 which were referred to the principal epidemic diseases, against 30 and 26 in the two preceding weeks; these 29 deaths were equal to an annual rate of 1·3 per 1000, the highest epidemic rates being 2·9 in Dublin and 7·1 in Londonderry. Of these 29 deaths from the principal epidemic diseases, 11 resulted from whooping-cough, 6 from scarlet fever, 4 from diarrhœa, 3 from enteric fever, 3 from diphtheria, and 2 from measles. The deaths from whooping-cough, which had been 18, 9, and 8 in the three preceding weeks, rose to 11 last week; 6 deaths were recorded in Dublin and 5 in Londonderry. The fatal cases of measles, scarlet fever, diphtheria, and 2 of the 3 deaths from enteric fever were registered in Dublin. In 20 of the 22 town districts no death from the principal epidemic diseases was recorded last week. The deaths in the 22 towns referred to diseases of the respiratory system, which had been 107 and 141 in the two preceding weeks, declined to 137 in the week under notice. The 507 deaths from all causes last week included 151, or 30 per cent., which occurred in public institutions. The causes of 17, or 3·4 per cent., of the deaths in the 22 towns last week were not certified either by a registered medical practitioner or by a coroner; the proportion of uncertified causes last week did not exceed 0·9 per cent. in the 77 English towns, but was equal to 2·7 per cent. in the principal Scotch towns.

### VITAL STATISTICS OF LONDON DURING 1910.

In the accompanying table statistics of sickness and mortality in the City of London and in each of the metropolitan boroughs are summarised for the year 1910. The mortality figures in the table relate to the deaths of persons actually belonging to the various boroughs, and are obtained by distributing the deaths in institutions among the several boroughs in which the deceased persons had previously resided; the death-rates from all causes are further corrected for variations in the sex and age constitution of the populations. With regard to the notified cases of infectious disease it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to a rate of 4·5 per 1000 of the population, estimated at 4,872,702 persons in the middle of last year; in the three preceding years the rates had been 8·6, 7·4, and 6·1 per 1000 respectively. Among the various boroughs the rates last year ranged from 2·6 in Hampstead, 3·1 in the City of Westminster, 3·2 in Chelsea, 3·3 in Kensington and in Stoke Newington, and 3·4 in Holborn, to 5·4 in Poplar and in Lewisham, 5·5 in Bethnal Green, 5·6 in Finsbury, 5·9 in Bermondsey, and 6·0 in Woolwich. Only 7 cases of small-pox were notified last year, against 8, 4, and 21 in the three preceding years; of these 7 cases, 2 belonged to Shoreditch and 1 each to Westminster, Islington, Poplar, Bermondsey, and Woolwich. Scarlet fever showed a markedly decreased prevalence, only 10,509 cases being notified, against 25,925, 22,072, and 17,251 in the three preceding years. Among the metropolitan boroughs this disease was proportionally most prevalent in Hammersmith, St. Pancras, Poplar, Bermondsey, Lambeth, Battersea, Lewisham, and Woolwich. There were 9889 scarlet fever patients admitted into the Metropolitan Asylums Hospitals last year, against 23,953, 20,862, and 16,183 in the three preceding years; 1574 cases remained under treatment at the end of the year, against 4956, 3498, and 2329 at the end of the three preceding years. Diphtheria also showed a decreased prevalence last year, the number of cases notified being 5494, against 8771, 8002, and 6685 in the three preceding years. The greatest proportional prevalence of this disease occurred in Fulham, Islington, Finsbury, Bethnal Green, Southwark, Bermondsey, Greenwich, and Lewisham. The Metropolitan Asylums Hospitals contained 827 diphtheria patients at the end of last year, against 1168, 1241, and 904 at the end of the three preceding years; the number of new cases admitted, which had been 7303, 6797, and 5799 in the three preceding years, declined to 4882 last year. Enteric fever was rather more prevalent than it had been in the preceding year; the number of notified cases of this disease, which had been 1394, 1357, and 1042 in the three preceding years, rose again to 1284 last year. This disease was proportionally most prevalent in Holborn, Finsbury, Shoreditch, Bethnal Green, Stepney, Poplar, and Bermondsey. The number of enteric fever patients admitted into the Metropolitan Asylums Hospitals during the year was 745, against 768, 708, and 539 in the three preceding years; 88 cases remained under treatment at the end of the year, against 119, 147, and 62 at the end of the three preceding years. The greatest proportional prevalence of erysipelas occurred in Hackney, Finsbury, Shoreditch, Bethnal Green, Stepney, Poplar, Southwark, Bermondsey, and Deptford. The 292 cases of puerperal fever notified during the year included 29 belonging to Stepney, 20 to Fulham, 20 to Islington, 20 to Wandsworth, and 19 to Lambeth. Of the 115 notified cases of cerebro-spinal meningitis 16 belonged to Islington, 10 to St. Pancras, and 7 each to Paddington, Fulham, Bethnal Green, and Stepney.

During the year under notice the deaths of 61,756 London

## ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING THE YEAR 1910.

*(Specially compiled for* THE LANCET.)

| CITIES AND BOROUGHS. | Estimated population in the middle of 1910. | NOTIFIED CASES OF INFECTIOUS DISEASE. | | | | | | | | | | | DEATHS FROM PRINCIPAL INFECTIOUS DISEASES. | | | | | | | | | | Deaths from all causes. | Death-rate per 1000 living.† |

* Including membranous croup.

† The death-rates are corrected for variations in sex- and age-constitution of the populations of the several boroughs, the population of England and Wales being taken as the standard.

residents were registered, being equal to a corrected death-rate of 13·3 per 1000, against 15·2, 14·4, and 14·6 in the three preceding years, the average rate for the ten years 1900–09 being 16·4 per 1000. Among the several boroughs the lowest death-rates last year were 9·7 in Hampstead, 10·0 in Lewisham, 10·7 in Wandsworth, 11·1 in Fulham, 11·2 in Woolwich, 11·5 in Stoke Newington, and 11·8 in Greenwich; and the highest rates 16·1 in Holborn, 16·6 in Southwark, 17·0 in the City of London, 17·5 in Shoreditch, and 18·1 in Finsbury and in Bermondsey. The deaths from all causes included 5558 which were referred to the principal infectious diseases; of these, 1980 resulted from measles, 214 from scarlet fever, 434 from diphtheria, 1362 from whooping-cough, 196 from enteric fever, 4 from ill-defined pyrexia, and 1368 from diarrhœa, but not any from small-pox or from typhus fever. These 5558 deaths were equal to a rate of 1·1 per 1000, the death-rate from the same diseases in the three preceding years being 1·4, 1·4, and 1·3 per 1000, and averaging 1·8 per 1000 for the ten years 1900–09. The death-rates last year from these diseases ranged from 0·5 in the City of Westminster, in Hampstead, and in the City of London, and 0·6 in Stoke Newington, Wandsworth, Lewisham, and Woolwich, to 1·5 in Poplar and in Deptford, 1·9 in Finsbury and in Shoreditch, 2·0 in Southwark, and 2·4 in Bermondsey. The 1980 deaths from measles were 100 in excess of the corrected average number for the five preceding years; this disease was proportionally most fatal in Hammersmith, St. Pancras, Finsbury, Shoreditch, Southwark, and Bermondsey. The 214 fatal cases of scarlet fever were 329 fewer than the corrected average number; the greatest proportional mortality from this disease occurred in St. Pancras, Bethnal Green, Poplar, Bermondsey, Lambeth, Lewisham, and Woolwich. The 434 deaths from diphtheria were 248 below the corrected average number; the highest death-rates from this disease were recorded in Hammersmith, Finsbury, Bethnal Green, Southwark, and Bermondsey. The 1362 fatal cases of whooping-cough showed a slight decline from the corrected average number; the greatest proportional mortality from this disease occurred in St. Pancras, Finsbury, Shoreditch, Stepney, Poplar, Deptford, and Greenwich. The 200 deaths referred to "fever" were 26 fewer than the corrected average number for the five preceding years; the highest "fever" death-rates were recorded in Holborn, the City of London, Shoreditch, Bethnal Green, and Poplar. The 1368 fatal cases of diarrhœa were equal to only one-half of the corrected average number; this disease was porportionally most fatal in Finsbury, Shoreditch, Stepney, Poplar, Southwark, Bermondsey, and Deptford. In conclusion, it may be stated that the aggregate mortality in London last year from these principal infectious diseases was 25·6 per cent. below the average for the five preceding years.

## THE SERVICES.

### ROYAL NAVY MEDICAL SERVICE.

THE following appointment has been notified:—Surgeon: G. P. Adshead to Haslar Hospital.

### ARMY MEDICAL SERVICE.

Colonel Thomas F. MacNeece, on completion of four years' service in his rank, retires on retired pay (dated Feb. 16th, 1911). Lieutenant-Colonel Henry H. Johnston, C.B., from the Royal Army Medical Corps, to be Colonel, vice T. F. MacNeece (dated Feb. 16th, 1911).

### ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel Richard E. R. Morse retires on retired pay (dated Feb. 18th, 1911).

The under-mentioned to be Lieutenants (on probation) (dated Jan. 27th, 1911): Benjamin Biggar, James Dunlop Kidd, Charles Morgan Finny, Gordon Wilson, William Struan Robertson Steven, Edward Geoffrey Stayner Cane, William Arthur Frost, Lieutenant William Thomson Graham (from the Royal Army Medical Corps Special Reserve), Francis Aidan Robinson, Douglas Reynolds, John Sutherland Levack, Pierce Morgan Joseph Brett, Patrick Hayes, Lieutenant Thomas Alexander Weston (from the Royal Army Medical Corps Special Reserve), Walter Bisset, Tom Chamney Russell Archer, William Lionel Evelyn Fretz, and Charles Douglas Kingsley Seaver.

The under-mentioned Lieutenants are seconded under the provisions of Article 300, Royal Warrant for Pay and Promotion, 1909 (dated Jan. 27th, 1911): Benjamin Biggar, John S. Levack, and Thomas A. Weston.

Colonel H. H. Johnston, C.B., from the Curragh, has been appointed Administrative Medical Officer at Chatham in succession to Colonel T. F. MacNeece. Colonel D. Wardrop, C.V.O., has been appointed House Governor and Medical Superintendent of the Convalescent Home for Officers at Osborne, in succession to Lieutenant-Colonel C. R. Kilkelly, C.M.G., M.V.O., resigned. Lieutenant-Colonel J. A. Jones has been selected for appointment as an Administrative Medical Officer of the Welsh Territorial Division, vice Colonel P. E. Hill, resigned. Lieutenant-Colonel G. F. Gubbin, on completion of a tour of service in India, has been posted to the Dublin District. Lieutenant-Colonel S. G. Allen, from the London District, has taken up duty at Gibraltar. Lieutenant-Colonel L T. M. Nash has been transferred from Hyderabad, Sind, to the Station Hospital at Karachi, relieving Lieutenant-Colonel R. L. R. Macleod, who has been posted to Aden. Major H. V. Prynne has taken over duty as Medical Officer in Charge of the Royal Military Academy at Woolwich, vice Major G. A. Moore, whose tenure of the appointment has expired. Major C. A. Young has been selected for appointment as Staff Officer to the Administrative Medical Officer of the Welsh Division at Shrewsbury, with effect from April 1st next. Major C. G. Spencer, from Queen Alexandra's Military Hospital, London, has taken up the appointment of Specialist in Advanced Operative Surgery at York. Major A. E. Thorp, from Tidworth Park, has joined for duty at Pretoria. Major J. F. Burke has been transferred from Lancaster to Falmouth. Major M. D. Erskine has been selected for appointment as Staff Officer to the Administrative Medical Officer of the Lowland Division. Major John M. Buist has taken over duty at Pontypridd from the Royal Victoria Hospital, Netley Abbey. Major J. S. Gaillie has been appointed Specialist in Dermatology and Venereal Diseases to the Sixth (Poona) Division. Captain A. W. Sampey, from Colchester, has taken over medical charge of the staff and families at Warley. Captain E. J. H. Luxmoore, on return from India, has been appointed for duty at the Military Hospital, Dover. Captain W. F. Tyndale, C.M.G., from the Curragh, has been posted to Dublin. Captain L. Bousfield has been transferred from Falmouth to Devonport. Captain D. O. Hyde, at present serving in Dublin, has been selected for appointment as Staff Officer to the Administrative Medical Officer of the West Riding Division at York, with effect from April 1st next. Captain A. McMunn has taken up duty at Portobello Barracks, Dublin. Captain S. M. Adye-Curran has taken over charge of the Brigade Research Laboratory at Sialkot. Captain D. P. Watson, from Pembroke Dock, has joined at Lancaster. The following officers (lieutenants) have, on arrival in India, been posted to Rawal Pindi to undergo a special course of instruction in Indian Sanitation: D. H. C. MacArthur, H. Gall, A. W. Byrne, and T. J. Mitchell. Lieutenant C. H. O'Rorke, from Newbridge, has taken up duty at the Curragh. Lieutenant J. A. Manifold has been transferred from Piershill to Fort George. Lieutenant J. B. Hanafin, from Sialkot, has been posted to Kalabagh. Lieutenant E C. Lambkin, from Windsor, has joined for duty at the Guards Depôt, Caterham.

### INDIAN MEDICAL SERVICE.

Lieutenant-Colonel J. R. Adie, Bengal Presidency, has been placed on special duty in connexion with the investigation of malarial fevers in India. Lieutenant-Colonel J. K. Close has arrived home on leave of absence from Bombay. Major E. Ludlow Perry has been placed at the disposal of the Sanitary Commissioner with the Government of India. Major A. H. Moorhead, Bengal, and Major J. C. H. Leicester, civil surgeon of Simla, have arrived home on leave of absence from India. Major F. N. Windsor has been transferred from Rangoon to Calcutta as Chemical Examiner. Major G. McI. C. Smith has been appointed Civil Surgeon at Shapur in succession to Captain W. W. Leudwine. Captain D. N. Anderson has been granted six months' extension of his leave on medical certificate by the Secretary of State for India. Captain T. F. Owens, chemical examiner and bacteriologist to the Government of Burma has been transferred for temporary inspection duty to Madras. Captain C. F. Weinman has been appointed to

officiate as Resident Physician at the Medical College Hospital, Calcutta, during the absence on deputation of Captain C. J. Coppinger. Captain C. A. F. Hingston, late medical officer of the 76th Punjabis, has been selected for duty in the Madras Presidency. Captain N. M. Wilson has been appointed Agency Surgeon at Meshed and Assistant to the Agent at Khorasan by the Foreign Department of the Government of India. Captain A. B. Fry has been appointed to act as an additional Deputy Secretary to the Commissioner in Bengal in connexion with the investigation of Malarial Fevers in India. Captain G. D. Franklin, Captain F. O. D. Fawcett, and Captain D. Munro have arrived home on leave of absence from India.

### TERRITORIAL FORCE.

*Royal Army Medical Corps.*

2nd Highland Field Ambulance, Royal Army Medical Corps: Major Alexander Ogston, from the 1st Highland Field Ambulance, Royal Army Medical Corps, to be Major (dated May 22nd, 1910).

2nd London (City of London) Field Ambulance, Royal Army Medical Corps: Frederic Morres to be Lieutenant (dated Dec. 10th, 1910).

1st Lowland Field Ambulance, Royal Army Medical Corps: Lieutenant Ernest A. Boxer resigns his commission (dated Feb. 18th, 1911).

1st Northumbrian Field Ambulance, Royal Army Medical Corps: Lieutenant Frederick G. Armstrong resigns his commission (dated Feb. 18th, 1911).

*Attached to Units other than Medical Units.*—Lieutenant Wilfred E. Alderson to be Captain (dated Oct. 26th, 1910). Lieutenant Frederick K. Smith to be Captain (dated Nov. 1st, 1910). Lieutenant-Colonel Duncan W. Currie resigns his commission, and is granted permission to retain his rank and to wear the prescribed uniform (dated Feb. 18th, 1911).

### DEATHS IN THE SERVICES.

The death of Charles Alexander MacMunn, M.D. Dub., at the age of 58 years, is announced. He took part in the South African War 1899–02, and was appointed by Lord Roberts as Staff Officer on the commission which inquired into the administration of the medical service during the war. He was medical attendant to Lord Roberts, was mentioned in despatches, and received the Queen's medal with three clasps. He was formerly colonel commandant of the branch of the Royal Army Medical Corps (Territorials) which he founded at Wolverhampton, and he also acted as brigade surgeon of the North Midland Division of the Territorial Force. He was a surgeon-lieutenant-colonel of the Army Medical Reserve, and held the Jubilee medal, the Volunteer long service decoration, and the Coronation medal.—Surgeon-Lieutenant-Colonel Henry Frank Hensman, C.M.G., late 1st Life Guards, at Rodbaston, Penkridge, Staffordshire, on Feb. 21st, aged 72 years. He entered the service as assistant surgeon in 1862 and retired in 1894. He served in the Umbeylu campaign on the North-west Frontier of India in 1863–4, and in the South African war in 1899–1900 (promoted colonel, mentioned in despatches, and received the C.M.G.). He was an Honorary Associate of the Order of St. John of Jerusalem.

### MEASLES AT THE NAVAL COLLEGES.

Replying to a question by Mr. W. T. Wilson in the House of Commons on Feb. 21st, Mr. McKenna said that the Admiralty had no reason to suppose that the firms employed by the parents of naval cadets to make uniforms did not take proper precautions for the protection of their customers, or that infectious disease had ever been introduced into the colleges by infected uniforms.

### THE RED CROSS IN THE FRANCO-GERMAN WAR.

Although some 40 years have passed away since the Franco-German war, the memories of 1870–71 still remain strong in the minds of those who remember the war, and cannot be recalled without a thrill of emotion by those who took part in it. The recollections of the medical side of the campaign, more especially as seen from the German lines, which Mr. Henry Rundle[1] has republished in book form, much of the matter for the small volume having already appeared in the *St. Bartholomew's Hospital Journal*, will be read from first page to last with increasing interest. Starting with a brief sketch of the events which led up to the quarrel between France and Germany, he describes how he, together with other volunteers, set out for the seat of war under the auspices of the Red Cross Society, and the part they played in ministering to the sick and wounded. Though the war was brief, its horrors were sufficiently great, but Mr. Rundle describes them without in any way harrowing the feelings of his readers. The book is well printed on thick paper, the type is large, the illustrations are good, and there is an introductory note by Professor Howard Marsh. Members of the various voluntary aid societies now being formed throughout the country will read this book with profit, as it practically illustrates some of the work of the Red Cross, "the one link that remains unbroken between nations" when wars arise. The profits on the sales of the book will be given to the building fund of the Nurses' Homes at the Royal Portsmouth Hospital, which is to be the Portsmouth memorial to King Edward VII.

At a meeting held at Truro on Feb. 18th for the purpose of forming a branch of the British Red Cross Society, Inspector-General A. W. May, R.N., said that Cornwall was far behind the rest of the country in the matter of voluntary aid associations.

# Correspondence.

"Audi alteram partem."

## THE CLIMATIC ADAPTATION OF THE IMMIGRANT.

*To the Editor of* THE LANCET.

SIR,—Your annotation on the above subject with reference to Major Woodruff's article in the *Eugenics Review* moves me to offer some comments. In a paper I read at the British Medical Association annual meeting in 1910 I traced the evolution of the blonde Nordic type, showing that, by reason of its development, its postulates for vigorous health are comparative dryness of soil and climate, plenty of elbow-room, a bright summer, and a frosty rather than a rainy winter.

Tacitus, in his celebrated treatise on the "Germans" (i.e., the various tribes of Nordic race), remarks: "It is well known that none of the German nations inhabit cities or even admit of contiguous settlements. They dwell scattered and separate, as a spring, a meadow, or a grove may chance to invite them. Their villages are laid out, not like ours in rows of adjoining buildings, but every one surrounds his house with a vacant space." This passage is of interest in view of the well-ascertained inability of blondes to adapt themselves to urban existence at the present day. As regards their susceptibility to sunlight, I have been making observations on this point for some years, and am convinced that so far from it having a deleterious effect on them they need plenty, provided it be not associated with tropical heat or great humidity.

The most popular holiday resorts of our upper classes, among whom the blonder British types are mostly found, are the east coast in summer, the high Alps in winter, the latter evidently ministering to some physiological need. The purest blonde types are found round the shores of the Baltic, and the climatic conditions prevailing there can be taken as a model for the requirements of this race. It is notable that the south-west of Norway, where there is a pelagic climate with high rainfall, is peopled by a race closely resembling that of the central mountain ranges of Europe—the Alpine type. Similarly, in Holland the brunets, are found on the damper levels west of the Zuyder Zee and in the cities, the blondes predominating in Friesland and other eastern districts. This is well shown in a map in Professor Ripley's "Races of Europe."

The dominant Australian type, the "Cornstalk," familiar to us in the Antipodean athletes, cricketers, &c., who visit England from time to time, is "Nordic" in type, the freer open-air life and dry climate favouring this race. The Boer is also mainly a Nordic with a strain of darker races, and here again the climate of the veldt presents most, if not all, of the requisite conditions. The Canadian plains also should provide a favourable environment for immigrants of

fair complexion, and such information as I have been able to obtain tends to confirm this opinion.

It is, however, unnecessary to go so far afield as the colonies to study the effects of migration. It confronts us at our very doors. The British people is largely a migrated community not yet fully adapted to its environment. When, however, the greater migrations into this country ended with the Normans, and local communities of mixed origin settled down into pastoral and agricultural pursuits, local types were gradually evolved through the circumscribed character of the said communities. These local types were, so to speak, specialised for particular climatic and social conditions, a variety of factors determining the preponderance of one or other racial type in surviving individuals.

In this way considerable progress must have been made towards a natural equilibrium of adaptation. At the beginning of the industrial era we were probably the most virile people in Europe. The rise of industrialism, however, together with greater facilities of transit, has signalised the disintegration of rural communities, the dislocation of rural types, and their migration into the cities, where the aggregation of mixed elements has been subjected to the stress of natural selection in a severe form pending the evolution of an industrial type.

Major Woodruff's suggested investigation among the "failures" has much to recommend it, but the difficulty lies in obtaining the coöperation of a sufficient number of adequately trained observers. When similar investigations have been attempted trouble has constantly arisen from disagreement as to standards, criteria, &c., and the inability to procure uniformly accurate returns. Your annotation closes with the suggestion that "the production of a higher mental type depends probably, at any rate in great degree, on first acquiring a physique perfectly adapted to its climatic environment." But surely the human brain has achieved its extraordinary development through man's long contention with environments to which he was *not* perfectly adapted, having left the regions of his origin to spread himself over the earth. It is only when he is crushed by too severe or sudden a change that he degenerates.

I am, Sir, yours faithfully,

Hampstead, N.W., Feb. 20th, 1911. J. S. MACKINTOSH.

## A COMBINATION TEST FOR COLOUR VISION.

*To the Editor of* THE LANCET.

SIR,—Some of your readers may remember seeing an article which I published in THE LANCET of July 15th, 1893, with this title. This article described a lantern which I had brought out, and which in many particulars anticipated the lantern which Dr. F. W. Edridge-Green described in his very interesting Hunterian lectures on Feb. 1st and 3rd.

My telechrome, as it is called, consists of an apparatus in which six colours—yellow, blue, pale green, signal-green, rose, and red—are shown by transmitted light to the patient through two apertures (one at a time, of course). One of these apertures is the perspective, when seen at 6 metres, of a 6-inch lamp at 100 yards; the other of the same lamp at 2000 yards. With the exception of purple, which I did not consider necessary, the colours are almost identical, it would appear, with those of Dr. Edridge-Green's.

My test possesses two points, however, which I think have an advantage over Dr. Edridge-Green's. The first is that the illumination can be readily varied, and this is important; while the second point is that the reflected colours from, say, a set of Holmgren's wools are shown to the patient at the same time—and he is required to compare the luminous colours of the telechrome with the non-luminous colours of the wools. If he should be faulty in either case the test detects the fact.

In other respects the telechrome may be used much as Dr. Edridge-Green uses his lantern. I also employ a "fogging" glass—and originally had a neutral tint modifier as well, but discarded it eventually, as I found that simple ground glass was apparently quite sufficient. May I add in conclusion that my telechrome has been used regularly at the Admiralty for many years, with (I am told) excellent results? Staff-Surgeon Preston, R.N., spoke very favourably of it upon the Commission on Colour Vision in 1892—as may be seen in the report of that committee published as a Blue-book—and it has continued to be in use ever since.

I am, Sir, yours faithfully,

A. ST. CLAIR BUXTON,

Consulting Surgeon to the Western Ophthalmic Hospital.

PS.—An illustrated leaflet on the telechrome may be obtained from Messrs. Curry and Paxton.

Mansfield-street, W., Feb. 16th, 1911.

## GIRLS' SCHOOLS, GAMES, AND NEURASTHENIA.

*To the Editor of* THE LANCET.

SIR,—It seems to me that Dr. Robert Jones has, in his letter in THE LANCET of Feb. 4th, to use a homely but expressive metaphor, got the wrong sow by the ear. It is true that in accounting for neurasthenia and disinclination for domestic life in girls educated in high-class schools, he mentions two factors—the nature of their studies and the nature of their games—but his letter is subsequently devoted wholly to inveighing against the latter. Now, if neurasthenia and disinclination for domestic life are particularly prevalent among this class of girls, I contend that it is more likely to be due to the first factor. Among the ancient Greeks, a people noted for even balance between and perfection of mind and body, the women were trained in gymnastics, and particular importance was attached to ball games. But is it among such girls, whose splendidly improved physique is the constant theme of all sufficiently long-lived observers, that neurasthenia, at any rate, is most prevalent? My experience is that it is among such a class as Board School mistresses of inferior physique, who have been exposed to severe mental competition, without the time and opportunity for games, that it is more often to be found.

I am, Sir, yours faithfully,

GILBERT E. MOULD.

The Grange, near Rotherham, Feb. 9th, 1911.

## EYE-STRAIN IN RELATION TO GENERAL HEALTH.

*To the Editor of* THE LANCET.

SIR,—In the article on the above-mentioned subject, contributed to this week's LANCET by Dr. James Hinshelwood, I find the following: "In fact, my experience is that the small amounts of astigmatism give rise to symptoms of discomfort more frequently than the high degrees. The explanation, I think, is that a person with a high degree of astigmatism makes no effort to see better, as his vision is so defective, *but that the smaller degrees of astigmatism, only causing a slight blurring, induce the patient to make a continuous accommodative effort to counteract it* and get clear images, and hence cause continuous ciliary strain." I do not wish, in criticising a very interesting paper, to be captious, but I certainly demur to that part of the extract I have italicised. The inference here plainly is that certain isolated fibres of the ciliary muscle are capable of independent action, so that a static corneal astigmatism can be neutralised by a dynamic lenticular astigmatism. The ciliary muscle (so far as its meridianal fibres are concerned) is one muscle controlled by one centre and not several muscles controlled by several centres. This being so, how can one part act independently of other parts? Will Dr. Hinshelwood kindly inform your many ophthalmic readers upon what recent investigations he bases his statement?

I am, Sir, yours faithfully,

London, Feb. 18th, 1911. KENNETH CAMPBELL.

## THE HYPERÆMIA TREATMENT OF UNUNITED FRACTURE.

*To the Editor of* THE LANCET.

SIR,—I am led by Mr. A. E. Barker's interesting narrative in THE LANCET of Feb. 4th, giving a series of cases occurring in his practice in which the hyperæmia treatment of ununited fracture was strikingly successful, to relate the following example of its application.

A middle-aged gentleman, the victim of melancholia, leaped from his bedroom window, a height of 30 feet, falling on the lawn, and striking in his fall his left forearm on the

edge of a garden box. Simple fracture of both bones midway between elbow and wrist was his only injury. Splints were applied from above the elbow to the finger-tips. Eight weeks later there was no sign of bony union, the lower segment rocking flailwise on the upper. The only change of treatment now made was the application, morning and evening, for three hours at a time, of a broad elastic band about the upper arm, maintained at such tension as to induce flushing and turgor, without œdema or pain. Within three weeks the solidarity of the forearm was restored and the fragments of each bone were found to be reunited.

In this case the methods advocated by Lucas-Championnière were not employed at any stage of the treatment, not that they were undervalued, but because the partial disablement of this suicidal patient so sensibly relieved the cares of the nurses, and justified such a relaxation of the restraints imposed upon the sufferer, that there was no strong motive for hastening the processes of repair. If the omission of these methods may help to account for the failure of bony union in the first eight weeks, it may fairly be argued that their continued omission during the three weeks of Bier's treatment speaks strongly in favour of induced hyperæmia.

I am, Sir, yours faithfully,

S. N. BRUCE, M.R.C.S. Eng.

Queensborough-terrace, W., Feb. 16th, 1911.

## CHARLES BELL AND THE MOTOR AND SENSORY FUNCTIONS OF SPINAL NERVES.

*To the Editor of* THE LANCET.

SIR,—While Professor Waller might have been justified (THE LANCET, Feb. 18th, p. 470) in presuming my ignorance of the statement made regarding the discoveries of Sir Charles Bell in his "Introduction to Human Physiology," he is under a misapprehension when he presumes my ignorance of the original works of Sir Charles Bell. Professor Waller must forgive me if I refuse to accept a quotation from his well-known text-book as authoritative. I do not recollect any statement by Sir Charles Bell in either the "Idea of a New Anatomy of the Brain" or in the paper in the Philosophical Transactions of 1821 which justifies Professor Waller's quotation that Sir Charles Bell "inferred that the anterior or 'cerebral' roots are motor and sensory and the posterior or cerebellar roots serve to govern vital actions." Before awakening the long-dead discussion regarding the priority of Magendie, whose claims were ardently advocated in 1822 by a former and somewhat unfriendly pupil of Bell's —Professor H. Mayo—it would be well for Professor Waller to quote, not from his own works, but from the original works of the author in dispute, so that readers of THE LANCET may form an unbiassed opinion as to the nature and time of Sir Charles Bell's discoveries.

I am, Sir, yours faithfully,

A. KEITH.

Royal College of Surgeons of England, Feb. 18th, 1911.

## THE SANITARY OFFICERS (OUTSIDE LONDON) ORDER, 1910.

*To the Editor of* THE LANCET.

SIR,—This important document, dated Dec. 13th, 1910, reached the local sanitary authorities concerned on Dec. 16th, 1910. It was accompanied by a circular dated Dec. 14th, 1910, and a memorandum vaguely dated "December, 1910." Throughout the Order the term "the Council" replaces that of "the Sanitary Authority," which was used in the Orders of March, 1891, which Orders are hereby rescinded. The Order came into force on Jan. 1st of this year, except Article X., which does not do so until April 1st, 1911. It is addressed to the councils not only of "municipal boroughs and other urban districts," but also to "the councils of the several rural districts" in England and Wales.

This new Order is not meeting with a cordial reception from medical officers of health or sanitary inspectors because, whilst making alterations in a few petty details, the great opportunity has been missed to rectify the mistakes and omissions of the old Orders. The medical officer of health or sanitary inspector who is too zealous or energetic is still left to the mercy of his laggard council, who can subject him to the indignity and risks of annual re-election as of yore. He now holds his important office only on tenure equivalent to an ordinary house tenancy. No qualification by examination is yet asked for from the candidates for inspectors' posts. So we shall still see blacksmiths, bankrupt farmers, corn dealers, &c., filling these appointments, where special knowledge of their work is absolutely necessary. Men who have studied their subject and proved their knowledge before the examiners of the Sanitary Inspectors' Board or the Royal Sanitary Institute will have no chance against the candidate who has local influence or, perhaps, is himself a member of the council requiring an inspector.

The Order does not define the municipal status of the medical officer, although the Circular states that "the inspector of nuisances, *as a rule*, should act under the supervision of the medical officer of health, who must be regarded as the head of the Public Health Department of the Council." (The italics are mine.) In other particulars the Order and the Circular are contradictory. This may be due to the haste with which the new Order was devised. Thus Article XX. (14) orders "that the inspector shall, if directed by the M.O.H.," &c.; the Circular says, "Article XX. (14) requires the officer, if so directed by the Council," &c. Which is the correct version? Again, Article XX. (16) of the Order says that the inspector shall furnish the medical officer of health, as soon as practicable after Dec. 31st in each year, particulars of the work he has done during the year; the Circular says, "By subclause 16 the inspector is to make an annual report to the Council on the work performed by him during the year." Which are we to stand by—the terms of the Order or the interpretation of the Order by the Circular? In the preamble (p. 2) of the Order the first word "county" in the penultimate line is a mistake for "municipal"—another specimen of hasty revision!

Of course, the Order places fresh duties on the officers concerned (see Articles XIX. (7), (13), (15), and XX. (14), (15), (16)), but by Article XIX. (14) the medical officer of health is spared the trouble of referring in his annual report to his council and the Local Government Board as to offensive trades, factories, and workshops in his district. He is also relieved from reporting anything about school closure to the Board. Why?

The *Memorandum* is important, as it records publicly the opinion of the Board that the appointment of part-time medical officers of health or sanitary inspectors is not to be desired. In either case it gives a list of other duties which (in the Board's opinion) may be allotted (in small districts) to these officers. I venture to think that few medical officers of health will agree that the duties of police surgeon (which are analogous to private practice) are compatible with their primary duty. These "omnibus" appointments, recommended though they are by the Local Government Board, are most undesirable, as they encourage pluralism and create officers who as regards any one of his several appointments would be "an official part-timer." Is this consistent on the part of the Board? In the Memorandum, too, the Board advocates adequate salaries, but at the same time, in the penultimate paragraph of p. 2, gives its approval to an iniquitous plan by means of which economical (or mean) authorities can and do arrange to give a part-time salary to a medical officer of health, who is not allowed to engage in private practice and yet cannot do anything practicable to supplement his inadequate salary, because his council takes care to give him enough work to occupy his *whole time*. In the last paragraph of the Memorandum the Board offers councils the most proper advice about the travelling expenses of the sanitary inspector. Why did not the Board offer the same with reference to medical officers, to whom the necessity of adequate travelling allowance, especially over large areas, is equally great?

In conclusion, Sir, let me remind you that it is nearly 20 years since the last Orders were issued. Perusal of the new Order will convince anyone that the Local Government Board has done thereby little or nothing to remove the difficulty of honest and efficient administration of the numerous Acts of Parliament, Regulations, Orders, &c., concerning the improvement of the public health. I am exceptionally situated for obtaining the views of many medical officers of health on matters concerning their arduous work, and I can therefore claim that the foregoing

criticism of the latest effusion of the Local Government Board is something more than a merely personal one.

I am, Sir, yours faithfully,

Feb. 13th, 1911. ENERGY.

## OMNOPON.

*To the Editor of* THE LANCET.

SIR,—I find that "pantopon" is now officially styled "*omnopon*," and Messrs. Hoffmann-La Roche, the sole makers of this preparation, have been good enough to supply me with samples of the drug under that name. They are in every way similar to the "pantopon" used in the cases referred to in my article, "Some Remarks on Pantopon Anæsthesia," and I should like to add that my remarks with regard to "pantopon" apply equally to "omnopon." The only difference is in the name, since I am told there is a legal difficulty in registering the name "pantopon" in this country. In justice to Messrs. Hoffmann-La Roche I hope you will be good enough to publish this addendum.

I am, Sir, yours faithfully,

Buckingham-street, W.C., Feb. 20th, 1911. C. LOUIS LEIPOLDT.

## BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

*Infants' Health Society.*

THE Birmingham Infants' Health Society, founded in 1907, is one of the most prominent of the agencies attempting to grapple with the problem of infant mortality. It concentrates its energies upon St. Bartholomew's Ward, where the infant mortality is particularly heavy, and endeavours not only to enlighten ignorant mothers as to their maternal duties, but to study at first hand the nature of the factors which give this ward an unenviable reputation. A considerable amount of apathy and prejudice has been overcome, and the annual report just issued gives abundant evidence of progress. At the weekly "infant consultations" where babies under 12 months of age are weighed and the mothers advised as to feeding, clothing, and general management, 411 children were examined last year, as compared with 353 in 1909 and 204 in 1908. The infant mortality among these "consultation infants" was 46·4, as against 201 for the whole of St. Bartholomew's Ward. The consultation mortality in 1908 was 95·2, and in 1909 49·8. The part played by feeding is strikingly illustrated by the fact that whereas there were only 8 deaths out of 171 breast-fed children, 7 bottle-fed children out of 53 died. Breast-fed babies 12 weeks old weighed on an average 4914 grammes, bottle-fed children of the same age 3813 grammes. At 12 months of age the difference was still more in favour of natural feeding. The effects of poverty on the physique of the child, even when breast-fed, are indicated in a series of tables contained in the report. Though practically all the mothers attending are in very poor circumstances, yet it is possible to divide them into two groups: (*a*) those distinctly suffering from poverty; and (*b*) those in slightly better circumstances. A three months old child belonging to group (*a*) fed at the breast weighs 4787 grammes, while the weight in group (*b*) was 5048 grammes. The average mortality-rate in St. Bartholomew's Ward for the five years ended Dec. 31st, 1909, was 205·8, and it is encouraging to note that the very class which in times past furnished the greater proportion of the infant mortality of the ward is the class which is now coming under the influence of the society. The society has "At Homes," at which the women learn knitting and sewing; evening educational classes, at which the lady superintendent, Miss Vine, instructs mothers in the feeding, bathing, and general management of babies; and also lectures on personal hygiene, home nursing, and cooking. The maternity department is very helpful to prospective mothers, and there is a system of home visitation which ensures proper attention for mother and child. At the annual meeting presided over by the Lady Mayoress, Dr. J. Robertson, medical officer of health, in moving the adoption of the report, said that, as to the methods of reducing infant mortality, he for many years sat on the hedge, and looking back he was not sure that he was not right, because many of the methods proposed 10 or 15 years ago had proved fallacious. Milk depôts where a pure article could be obtained at a cheap rate were supposed to be the method of dealing satisfactorily with the problem, but the Birmingham figures showed all along that the babies did not die because they got bad milk. By the health visitors they found that those districts where ignorance, carelessness, and poverty prevailed were associated with high mortality. If they could do something to stop babies from dying they also did much more for those who survived but whose lives at present were more or less wrecked by carelessness on the part of the mothers. There was a large proportion of babies who weathered the storm of the first year but who grew up into stunted men and women. Mr. Steel-Maitland, M.P., in supporting the resolution, referred to two dangers which occurred when public attention was attracted to a particular subject. One was what he might call washy semi-scientific talk and the other sentimental talk actuated by no wish for knowledge and activities directed by no knowledge. There was hardly any subject, he thought, about which these two faults were more apparent than the birth-rate. Many people uttered a dirge over the decline in the rate, while others regarded it as a good sign. There could be no doubt that if the birth-rate continued to fall without any counteracting influences, it would be a great disadvantage. There was ample room in this country for a vaster population if properly organised, while in our dominions abroad the room was unlimited. They wanted, not so much that the birth-rate should not decrease, but that the survival-rate of the adult active population should increase. Greater attention, he considered, should be paid to the ante-natal influence in mothers who had to go to work.

*Staffordshire and King Edward Memorial.*

A meeting to consider the proposal for a scheme to deal with consumption in Staffordshire as a memorial to the late King was held on Feb. 11th, at Stafford, under the presidency of the Lord Lieutenant, Lord Dartmouth. Dr. G. Reid, the county medical officer of health, had drawn up a memorandum on the question. In the course of it Dr. Reid stated that the results obtained by the sanatorium method of treatment had not so far justified the enthusiasm with which it was at first advocated. Experience showed that, with the inadequate means at present available of getting to know of cases early enough, in only about one-fifth of the definite cases could one look for really successful results from such treatment. On the other hand, a sanatorium used for isolation purposes was of great value, because the chief danger of infection was home contact, and the incurable cases were the most dangerous. No matter what form of treatment was adopted, some machinery for home supervision and the detection of the disease in its early stage must be provided. No matter how far local authorities might be induced to go in their efforts to deal with the problem, there would be ample scope for philanthropic help, and he suggested that any fund which might be collected in the county should be utilised in that direction. By means of such a fund it would be possible to organise a system by which, with the coöperation of local nursing associations, subsidised by the local health authorities, district nurses might be employed as house visitors to act under the direction of the medical officers of health, whom they would keep informed regarding the progress of cases which had undergone treatment. The nurses would also exercise supervision with the families as regarded home preventive measures and note from time to time any signs of ill-health suggestive of commencing consumption, in order that, if verified by medical examination, early, and therefore far more effective, steps might be taken in the way of treatment. It would be necessary to have classes for nurses to instruct them in their duties. The organisation of such a scheme might be entrusted to the County Nursing Association, and arrangements could also be made for lectures to be given in populous centres. The following resolutions were passed at the meeting:—

(1) That it was not advisable that the fund to be raised in the county should be utilised for the assistance of institutions already in existence; (2) that a fund be raised to be known as the King Edward VII. Tuberculosis Prevention Fund, and that it be utilised from time to time towards the cost of general measures for combating tuberculosis; and that (3) having regard to future possibilities, it is not considered expedient to expend any monies in the erection of a sanatorium at present.

Feb. 20th.

## LEEDS.

(FROM OUR OWN CORRESPONDENT.)

*King Edward West Riding Memorial Fund: Special Effort in connexion with the General Infirmary at Leeds.*

A MEETING convened by Lord Harewood, Lord Lieutenant of the West Riding, after consultation with the Lord Mayor of Leeds, was held in the town-hall, Leeds, recently, at which it was decided that the most appropriate memorial the West Riding could raise to the memory of King Edward would be a large fund for the subsidising of the hospitals in the West Riding. It was specially emphasised at the meeting that it was not desired in any way in thus making a general fund to interfere with or dilute the efforts of the larger towns in the same direction, and it was arranged that anyone who became a subscriber to the general fund could allocate his subscription to any hospital or infirmary in which he was more particularly interested. For some time it has been known that a large appeal would require to be made on behalf of the General Infirmary at Leeds, and the chairman, Mr. Charles Lupton, as the result of a personal canvass which he has undertaken, has secured promises of £56,000 towards the funds of that institution. The Lord Mayor of Leeds, Mr. W. Middlebrook, M.P., and Mr. Lupton, having held a consultation on the matter, the former called a meeting of those interested in the infirmary, and made the proposal that Leeds should coöperate with the West Riding in raising a large sum, and that the citizens of Leeds should be recommended to allocate their subscriptions to the uses of the General Infirmary at Leeds. This was agreed to, and the handsome nucleus of £56,000, all of which, of course, is allocated to the infirmary, goes to swell the West Riding fund. Since the opening of the Lord Mayor's fund this special Leeds portion has increased to nearly £70,000. No worthier memorial could be raised to the honoured memory of our late King, and it is earnestly to be hoped that throughout the Riding strenuous efforts will be made to secure a sum worthy of the occasion and in some degree adequate to the magnitude of the demands. In regard to the General Infirmary at Leeds, so well known throughout the country, it may be well to note that its development has been steady and rapid since that memorable occasion, now 143 years ago, when the following minute of a meeting held in an inn in Upperhead-row marked its inception: "That Mr. Andrew Wilson's house in Kirkgate be taken for an infirmary at £16 by the year." The buildings, sites, and furniture of the infirmary now represent a capital expenditure of £250,286, and there is urgent need for further extension and development. The expenditure is in excess of the income, and is bound to increase when these extensions are carried out. Among the more important requirements are the provision of four new operating theatres, the extension of the laboratory and pathological departments, the provision of additional accommodation for nurses, the provision of two additional wards, and the modernising of some of the wards. It must be remembered that the greater part of the present building is now about 45 years old, and structural alterations and repairs become decade by decade an increasing source of expense. The recent fire at the infirmary, happily unattended with loss of life, which was commented on in your columns, has emphasised the necessity of there being greater facilities for the removal of the patients in the event of a catastrophe, and has drawn attention to the existence of certain defects in construction which may be removed at some expense, and which must be rectified if all due precautions are to be taken against such a disaster. It had therefore some months ago been decided by the authorities of the infirmary that an appeal should be made to the public of Leeds, of the West Riding, and of Yorkshire generally for a sum of not less than £150,000. Unless this is forthcoming there must of necessity be some arrest of development and some crippling of the work of this, the greatest of the charities of Yorkshire. The appeal is to Yorkshire, but it must be remembered that many of the patients who are treated within the walls of the infirmary, both on the medical and on the surgical side, come from beyond the limits of Yorkshire, and it is hoped that many subscriptions may be obtained from areas outside that of the three Ridings. The connexion of the infirmary with the medical school, now a part of the University of Leeds, has been productive of much mutual benefit, and all who are acquainted with the methods of medical education will cordially endorse the statement that it is doubtful if there is a single family in Yorkshire which cannot trace some benefit it has received to the work carried on at the Leeds Infirmary. The infirmary is fortunate in having at the head of its board, in the person of Mr. Charles Lupton, a man thoroughly versed in hospital management and fully alive to the necessity of continuous development along the lines of scientific advance. He has, as he remarked once to your correspondent, determined that, when the time comes for him to resign the important position he holds he must have the satisfaction of feeling that the General Infirmary at Leeds is an institution thoroughly modern in equipment and abreast with the best standard of efficiency.

Feb. 20th.

## NEWCASTLE-ON-TYNE.

(FROM OUR OWN CORRESPONDENT.)

*Durham University College of Medicine.*

THE annual Court of Governors of the above College was held on Feb. 9th, under the presidency of Sir George Hare Philipson. Amongst others present were Councillor Johnstone Wallace, Alderman Sutton, Mr. Cecil Cochrane, Professor R. Howden, and Professor R. P. R. Lyle. Apologies for absence were read from the Duke of Northumberland, Viscount Ridley, the Lord Mayor of Newcastle, Sir Hugh Bell, and Mr. A. F. Ericsson. The annual report was read by the secretary, Professor Howden, and stated that during the past year the College had been recognised by the Board of Education as a technical institution and had received a grant of £36. It was confidently hoped that the grant for the current year would be much larger. In order to clear off a deficit which had been made necessary by the establishment of a suspense account, which the Board of Education desired, an appeal had been made for subscriptions which so far had resulted in the collection of £1229. The entry of students was satisfactory, though not quite up to the previous year. Mr. H. Brunton Angus had been appointed lecturer in surgery; Dr. T. Beattie professor of therapeutics, and Dr. William E. Hume lecturer in materia medica. Mr. Frank Howson, the lecturer in physiology, had been appointed to a post in the University of Sydney and steps were being taken to appoint a successor, while the Joint Pathological Board of the Royal Victoria Infirmary and the College of Medicine had advertised for an assistant to the professor of pathology. The report was adopted on the motion of Sir George Hare Philipson. At the council meeting of the College a letter was read from Dr. H. E. Armstrong, stating that, owing to pressure of public engagements and other circumstances, he had decided to resign his position as lecturer and examiner in hygiene, but he would hold office until the end of September. The letter was received with regret and a suitable resolution was framed and carried referring to Dr. Armstrong's valuable services over the long period of 38 years to the College and the esteem in which he was held by his colleagues.

*Past and Present Students' Dinner, College of Medicine.*

This dinner was held on Feb. 15th, the guest of the evening being Mr. W. Arbuthnot Lane, of Guy's Hospital, London. The chair was occupied by Mr. H. B. Angus, and the company included Sir George Hare Philipson (President of the College), Professor Howden, Professor Lyle, Professor Bolam, and Professor Hutchens. After the loyal toast, the health of the guest was proposed by the chairman, and suitably replied to by Mr. Lane. In the afternoon of the same day Mr. Lane gave an address in the College of Medicine on "Some Methods of Treating Fractures." This was well attended and received with interest and enthusiasm.

*Royal Victoria Infirmary.*

During the past week there has appeared in the local press a short statement that the difficulties between the honorary staff and the house committee had been settled. Owing to the decision of the honorary staff to maintain silence as to its differences with the committee no information other than sketchy references to the matter in the newspapers has been available. It appears, however, that in December last the honorary staff took exception to some statements in connexion with a report submitted to the house committee by the patients

admission committee, with the result that the resignation of the staff was handed in. It is now officially stated in the press that the resignations of the staff have been withdrawn, the committee having withdrawn the statements complained of and rescinded a resolution adopted as to a scheme of admission of patients, and that the honorary staff had agreed to meet the house committee to discuss the admission of patients. There is general satisfaction in the city and district over this happy issue from the difficulty.

Feb. 20th.

## SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

*The Royal Medical Society of Edinburgh.*

THE annual dinner of the Royal Medical Society of Edinburgh was held in the society's rooms on the evening of Feb. 15th, Dr. Francis R. Fraser, Senior President, being in the chair. The guest of the evening was Sir James Crichton-Browne. The President referred to the unavoidable absence, owing to professional and Parliamentary business, of Sir Robert Finlay, who had intended to be present that night. In proposing the toast of "The Guest" he said that 52 years ago a seat in that hall had been requested for Mr. James Crichton-Browne. A year later that gentleman was secretary of the society, and in the year 1860–61 he had been one of the presidents of the society. Sir James Crichton-Browne, as Vice-President of the Royal Institution for more than 20 years, had endeavoured to acquaint the public with the discoveries of medical and scientific research. Sir James Crichton-Browne, who was received with loud applause, spoke of the memories conjured up in those surroundings by old associations rising from the depths of memory. He spoke at length of the work of one of his *confrères* in the Royal Medical Society, James Bell Pettigrew, who became professor of medicine in the University of St. Andrews, and who was admitted to the Royal Medical Society immediately after he had won the Goodsir gold medal for his essay on the "Muscular Structure of the Heart." He remembered how at one of the society's meetings Pettigrew had vaguely adumbrated his theory of flight, and referred to his discovery of the figure-of-eight movements of the wings of birds and insects—a discovery which, in his opinion, was at the root of modern aviation. In 1873 Pettigrew published his book on "Animal Locomotion," a work which anticipated much which had now been accomplished, and much which was still to come. In conclusion, Sir James Crichton-Browne proposed the toast of "The Royal Medical Society." He referred to the fact that the President that evening was the son of his lifelong friend Sir Thomas Fraser. His earnest wish was that the society might continue to prosper.

*Scottish Birth-rate.*

In the Registrar-General's returns for Scotland for the quarter ending Dec. 31st, 1910, it is shown that the equivalent annual birth-rate is 23·9 per 1000 of the estimated population, a rate 2·9 less than the mean of the birth-rates of the fourth quarter of the preceding ten years, and the lowest quarterly birth-rate recorded in these reports, that is, since 1855. The equivalent annual death-rate is 14·3 per 1000 of the estimated population, which is the lowest Scottish death-rate of any fourth quarter.

*Edinburgh Indian Medical Service Dinner.*

There was no Edinburgh Indian Medical Service dinner last year owing to the lamented death of H.M. King Edward. It is proposed to hold the dinner this year as usual at the Caledonian United Service Club, Edinburgh, on the last Friday in May. It is hoped that Sir Alexander Christison will again be chairman. Further particulars may be obtained from Lieutenant Colonel J. Arnott, I.M.S., retired, 8, Rothesay-place, Edinburgh.

*Sutherland and Caithness Medical Officerships.*

On Feb. 17th a special meeting of the county council of Sutherland was held at Golspie, when a letter from Dr. G. Dick, medical officer of health, was under consideration. An offer had been made by the Caithness County Council and the Caithness County Committee to appoint Dr. Dick medical officer of health and school medical officer for the county of Caithness alone. By reason of the connexion in the matter of the medical officership of health between the two counties there has been some difficulty in arranging matters, and the decision reached by the meeting brings to a satisfactory point negotiations which have been going on for over a year. The meeting decided to separate the posts of medical officer of health for the counties of Sutherland and Caithness, and that the posts of medical officer of health and medical inspector of schools for Sutherland should be held together. It was also decided that a committee of eight members should be appointed to act as a joint committee along with eight members from the county committee on secondary education, with full powers, after Dr. Dick had sent in his resignation, to arrange terms and conditions for the appointment of a medical officer for the combined offices and to make the appointment.

*New Perth Infirmary.*

The annual meeting of subscribers to Perth Infirmary was held on Feb. 13th. The total number of cases treated last year was 3697, 342 fewer than the previous year. The ordinary income was £4260, and the expenditure £4441, leaving a deficiency of £181, which was, however, covered by legacies received. It is hoped that the new infirmary may be on the way next month. The estimated cost is £36,190, to meet which there is a sum of £33,012 available. Private offers have been made for the present infirmary, but the directors mean to expose it for public sale.

*Death of Dr. Duncan Sinclair Kennedy of Perth.*

The death of Dr. Duncan Sinclair Kennedy occurred at his residence, Perth, on Feb. 17th, at the age of 60 years. Dr. Kennedy was a native of Oban, and went to Perth 30 years ago, when he took over the practice of the late Dr. Nairn. He held for several years the post of indoor medical officer for the Perth parish council. He was also public health and medical officer of the burgh of Auchterarder. He was at his death an elder of St. John's parish church, which he joined from the "Wee Frees," being out of sympathy with their leaders. Dr. Kennedy was highly respected in the community. He leaves a widow and a grown-up family.

*Medical Officer Appointed to Aberdeen Poorhouse.*

At a meeting of the Aberdeen parish council held on Feb. 14th Dr. Clifford Bell was appointed resident medical officer. Dr. Bell graduated at Aberdeen University in 1896 and started practice in Aberdeen a little over ten years ago, and at present holds the appointment of assistant medical electrician at the Aberdeen Royal Infirmary. The duties of the new medical officer have been embodied in a set of rules. With regard to post-mortem examinations it is provided that he shall make a post-mortem examination of a body when called upon to do so by the procurator-fiscal, or if the procurator-fiscal intimates that he does not require a post-mortem examination, he shall make such examination if he is of opinion that it is necessary, provided always that the consent of relatives (if any) has first been obtained. It is reported by the poorhouse committee of the Aberdeen parish council that the following letter has been received by the inspector from the Local Government Board:—

> With reference to your letter dated 11th inst., I am instructed to say that the Board are gratified to learn that the parish council of Aberdeen have decided to appoint an additional resident medical officer at Old Mill Poorhouse. The Board accordingly sanction a salary for the senior resident medical officer at the rate of £200 per annum, in addition to board and apartments. Kindly inform me what amount it is proposed to claim against the medical relief grant in respect of board and apartments. I append a note showing what is allowed in similar circumstances in other poorhouses.

With regard to the last paragraph of the above letter the board recommends that £1 per week should be claimed for the board and lodging of the male resident in the Aberdeen poorhouse. This is the charge made against the Government grant for the resident's board in Dundee East poorhouse, Craiglochart, Craigleith, Stobhill, and Barnhill poorhouses, as seen from the list accompanying the letter.

Feb. 21st.

CATS AND DIPHTHERIA.—Mr. H. Ubsdell, the medical officer of health for the Buckfastleigh (Devon) urban district council, in his annual report for 1910 states that during the year 17 cases of diphtheria were notified. Mr. Ubsdell is of opinion, verified by post-mortem examination, that three of the cases were due to contagion from a cat.

# IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

*Irish Medical Association and Parliamentary Representation.*

THE Irish Medical Association, in common with other professional bodies, has often felt the disadvantage under which medical men suffer in their lack of representation in Parliament. For some time it has had under consideration the best method of obtaining for the interests of the profession in Ireland a hearing in the House of Commons. At the last meeting of the council of the association the following resolution was passed unanimously :—

That we are in favour of approaching at least two Members of Parliament to represent the interests of the Irish Medical Association in Parliament.

It is understood that the council is already in touch with two Members of Parliament, one on each side in party politics, who are willing to act as spokesmen for the profession when matters concerning its interests are under discussion.

*Boycotting of Irish Qualifications.*

The Council of the Association of Fellows of the Royal College of Surgeons in Ireland, a body which charges itself with the protection of the interests of the Fellows, has recently brought out a pamphlet dealing with the exclusion of candidates holding Irish qualifications from competition for certain posts in English hospitals. Detailed reference is given to the case of the Manchester Royal Infirmary which recently demanded Fellowship of the Royal College of Surgeons of England as a necessary qualification for candidates for an assistant surgeoncy. It is stated that similar demands have been made by the Queen's Hospital for Children, Bethnal Green ; Cancer Hospital, Fulham-road ; Seamen's Hospital, Greenwich ; King's College Hospital, London ; Manchester Children's Hospital ; and the Royal Waterloo Hospital, London.

*Infective Disease in Dublin.*

The outbreak of infective disease shows some signs of abatement, coincident, apparently, with the close of the dry spell which had lasted nearly since the beginning of the year. The death-rate from all causes for the week ending Feb. 11th was 30·6 per 1000 per annum, and from infective diseases 2·3 per 1000 per annum. From the beginning of the year up to Feb. 15th 63 deaths have taken place from the four diseases—scarlet fever, diphtheria, typhoid fever, and whooping-cough. Measles was responsible for many more. Sir Charles Cameron, medical officer of health, has addressed a letter to the daily papers stating that most of the cases of disease have been among the middle classes and well-to-do working people rather than among the very poor, and on the outskirts of the city rather than in the slums.

*Compliment to Sir Charles Cameron.*

A special meeting of the Dublin city council was held on Feb. 20th to witness the signing by Sir Charles Cameron of the roll of honorary burgesses of the city, and to present him with a casket containing the certificate of honorary freedom. The resolution conferring the honour on Sir Charles Cameron had been passed some months ago. Sir Charles Cameron, who is 80 years of age, has been medical officer of health of Dublin since 1862.

*Honorary Medical Degrees.*

At an extraordinary meeting of Convocation of the Queen's University of Belfast, held in the large hall of the University on Feb. 4th, the Right Hon. Thomas Sinclair, presiding over a large attendence, Dr. R. W. Leslie proposed, and Dr. W. Calwell seconded, the following resolution, of which due notice had been given :—

That we, Convocation of Queen's University of Belfast, emphatically protest against the disability imposed on the University by the Statutes, Chap. XXXIII., Clause (1), which prohibits the conferring of honorary degrees in the Faculty of Medicine ; and, having regard to the fact that this privilege was exercised respectively by the old Queen's University and by the Royal University throughout their careers and is enjoyed to-day by the University of Dublin, by the National University, and by the Royal College of Physicians and Surgeons in Ireland, we call upon the Senate to take such steps by appeal to the Privy Council or otherwise as will remove this anomalous disability.

The resolution was passed unanimously. In Ireland every university and examining medical college has had in the past the power of conferring a honorary medical degree or Fellowship. When the Royal University was abolished and in its place the two new institutions—the National and the Queen's Universities—were established, the Commission which drew up the statutes of the National University—presided over by Chief Baron Palles, and of which Dr. B. C. A. Windle and Dr. D. J. Coffey were the medical members—gave that body the option of conferring honorary medical degrees ; while the Belfast Commission, of which Sir Donald MacAlister, K.C.B., and Dr. J. Symington were the medical members, drew up the following Statute :—

The Senate may confer honorary degrees other than degrees in the Faculty of Medicine upon persons of distinction in letters, art, science, professional life, or the service of the public, and upon eminent benefactors of the University.

This provision, which distinctly forbids the conferring of honorary medical degrees, has caused great dissatisfaction to the medical profession in the North of Ireland.

*Sanitary Congresses in Ireland.*

The public health committee of the Edinburgh town council has decided not to send delegates either to the Conference of the Royal Institute of Public Health in Dublin next August, or to the Royal Sanitary Institute Congress in July at Belfast. The holding of two conferences in one year is looked upon as a needless waste of expenditure. It certainly seems ridiculous to hold two sanitary congresses in Ireland in two successive months.

Feb. 20th.

# PARIS.

(FROM OUR OWN CORRESPONDENT.)

*A Military Medical Officer threatened with an Action-at-law.*

AN officer of the colonial military force who has been under treatment at the Hospital of Val de Grâce, in Paris, since April, 1907, has recently made application to the Procureur of the Republic for legal assistance to enable him to bring an action for damages against a member of the medical staff of the hospital. He was admitted on account of spasmodic paresis of the upper limbs and he complains that the medical man treated him with injections of excessive doses of anilarseniate of soda, the result being that he immediately lost the use of his lower limbs. An inquiry which was held in February, 1909, by the Minister of War exonerated the medical man, but the patient says that he is applying to the law courts because the inquiry was biassed and he had not an opportunity of proving his statements.

*A New Application of Radiography.*

At a recent meeting of the Academy of Sciences M. Vaillant said that by means of radiography it was, he believed, possible to ascertain whether an infant had lived or not. When the infant had been born alive the abdominal organs—i.e., the stomach and intestines—were visible in the radiographic picture, but when the infant had not been born alive these organs were not shown in the picture.

*Chronic Appendicitis simulating Pulmonary Tuberculosis.*

In a communication made to the Société Médicale des Hôpitaux on Jan. 28th M. Faisans said that he had frequently observed patients who presented many of the signs of pulmonary tuberculosis, such as loss of flesh during successive short periods, progressive lassitude, pain in the right side of the back, cough without expectoration, long-continued pyrexia, and short febrile attacks after walking. In some cases there were physical signs in the lungs, including subcrepitant râles, a rough murmur at the right base, and a diminution of the vesicular murmur at the right apex. These physical signs did not last long, rather taking the form of sudden short attacks. The symptoms might lead to an erroneous diagnosis of tuberculous disease of the lungs, but they were in reality often due to chronic appendicitis, and the usual signs might be elicited at MacBurney's point. M. Faisans said that these patients ought to be operated on, the result being usually favourable, and one of the subsequent speakers, M. Comby Siredey, concurred in this opinion.

*Treatment of Cerebral Tumours.*

Speaking at the same meeting, M. Sicard described some cases of cerebral tumour in which localised cranial headache, either spontaneous or elicited by percussion or the use of a

large tuning-fork, served to indicate the position of the new growth. He spoke very highly of the information which radiography was capable of giving with regard to both the nature and position of the tumour. A whitish mark on the negative plate, indicating rarefaction and osseous eburnation, made it almost certain that the tumour was malignant. With regard to treatment, he advised decompressive craniectomy. He also recommended the judicious employment of lumbar puncture as a means of accustoming the nervous centres to the shock of operation. When the growth was comparatively superficial he was in favour of applying radiotherapy through an aperture in the cranium, the nervous ectoderm being less sensitive to the X rays than the cutaneous ectoderm.

*Freund's Operation for Pulmonary Œdema.*

Two patients on whom M. Tuffier had performed Freund's operation for pulmonary œdema have been shown by him at a meeting of the Surgical Society. The operations had taken place more than 18 months ago. The first patient was a woman, aged 28 years, who when she came under M. Tuffier's care was no longer able to work and had to pass her time sitting up in bed. He resected the first, second, third, fourth, fifth, and sixth costal cartilages on the right side, and since that time she had been able to earn her livelihood without a single day's interruption. The second patient was a man in the state of cyanosis and permanent respiratory anxiety characteristic of the last stage of emphysema. M. Tuffier performed bilateral resection of all the costal cartilages, and the man has now for two winters been employed as the chauffeur of a taxicab without having ever had to leave off work.

*Treatment of a Bullet Wound of the Stomach.*

At a meeting of the same society M. Hartmann communicated on behalf of M. Baudet a case in which a woman was shot with a revolver on a level with the eighth left intercostal space. Vomiting of blood showed that the bullet had penetrated the stomach. At the end of two and a half hours after the injury an incision was made parallel to the costal margin, the cartilages were divided as far as the seventh rib, and a flap which was made was turned up; the wound where the bullet entered the stomach then came into view and was sutured. The patient recovered. M. Hartmann called attention to the fact that only one wound of the stomach had been sutured, although there must have been another, because radiography showed that the ball was lodged near the vertebral column.

*Number of Medical Students in France.*

According to the official report, in the year 1910 there were 3756 registered students of medicine, being an increase of 346 over the number for the previous year. These 3756 students included 3330 men and 426 women; classified according to nationality, there were 3020 French students, of whom 124 were women, and 736 foreigners, of whom 302 were women. Of the total number of students, one-fifth were therefore foreigners.

(FROM OUR OWN CORRESPONDENT.)

*Statistics of the German Universities.*

ACCORDING to the *Deutsche Medizinische Wochenschrift* the number of students attending the German universities has increased from 13,000 in 1871 to 54,822 in the present year. From 1910 to 1911 there was an increase of 2415, the same as for 1909 to 1910. A similar desire for a university education exists in foreign countries also: in France, for instance, the number of students is estimated at about 42,000. Of the students in the German universities, 52,404 are men and 2418 are women, as compared with 50,557 men and 1850 women in the previous year. The number of medical students is rising, being 11,240, as compared with 10,135 in the previous year and 8088 five years ago. A similar increase has occurred among the students of philology, philosophy, and history. The number of students of theology, which has of recent years been lower than in any preceding period, begins to rise again, being 2535 for Protestant and 1766 for Roman Catholic theology. The number of law students has decreased from 12,160 to 10,890, that of dental students from 1395 to 1146, and that of pharmaceutical students from 1279 to 954. The three largest universities are those of Berlin with 9686 students, Munich with 6905, and Leipsic with 4900 students; the three smaller are those of Erlangen with 1011 students, Greifswald with 948, and Rostock with 816. In addition to the duly matriculated students 3528 men and 1772 women were granted permission to attend the lectures, so that a total number of 60,552 persons received instruction in various branches of knowledge at the universities. Of the matriculated students, 841 men and 103 women were foreigners, of whom no less than 406 men and 74 women were Russians; 39 men and 8 women were British; and 145 men and 65 women were American. The number of women students continues to increase, so that they now form 4·4 per cent. of the general body of students as compared with 3·5 per cent. in the previous year. The distribution of the women students among the various faculties of the universities is as follows: 1370 are students of philosophy, history, and similar subjects, as compared with 975 in the previous year; 527 are medical students, as compared with 476 in the previous year; 356 are students of mathematics and natural sciences, as compared with 287 in the previous year; 49 study dentistry; 60 study political economy and agriculture; 7 study theology; and 5 study pharmacy. The female students show a decided preference for the University of Berlin, 806, or about one-third of the total number of female students, being matriculated there. Together with the 1772 who, without being duly matriculated, are admitted to attend the lectures, the female students at the German universities have now reached the record number of 4184.

*Conviction of a Quack.*

Prosecutions of irregular practitioners in Germany have hitherto usually resulted in an acquittal, but in a recent case the offender was less fortunate. The circumstances were as follows. A woman suffering from a cancer of the mamma had consulted a surgeon who advised an operation. She then saw a well-known quack, who said that she could be restored to health by medicine without operation and he prescribed something for her, but she died within a year. The public prosecutor then charged the quack with having caused death by negligence. When brought to trial the accused pleaded that the success of an operation for cancer was always very doubtful, and that the woman might have died from the cancer even if she had been operated on. The surgeon gave evidence to the effect that the disease was in an early stage when he first saw her, that he had advised an operation, and that in his opinion the performance of the operation would have postponed the fatal issue for some years. According to his experience and that of other surgeons he was sure that the patient might have been saved, or at least the fatal issue postponed for years, if she had been operated on in due time. The court found the prisoner guilty of having caused death by negligence and condemned him to six months' imprisonment. This decision is rather remarkable as the courts have hitherto, as a rule, given a verdict of not guilty when a quack was charged not with direct neglect but only with giving wrong advice as in the above case. In Germany there is an unfortunate tendency to sympathise with medical impostors, and the confidence which some of the better classes place in them has even been shown during the discussions on the new anti-quackery Bill now under consideration by a committee of the Reichstag.

*Malignant Growths treated by Radium.*

At a recent meeting of the Berlin Medical Society Dr. Arendt read a paper on the effects produced by radium rays acting on malignant growths of the female genitals. For this purpose he used an ore of uranium obtained from Joachimsthal in Bohemia. The powdered mineral was put into an elongated pouch made of a very thin flexible material, and this pouch, after being coated with iodoform, was introduced into the vagina. At the commencement of the treatment the carcinomatous tissue must be removed as much as possible by means of a curette, and then cauterised with Paquelin's apparatus. The application of the radium-containing substance was begun two days afterwards, the pouches being changed every third day. The treatment had a distinctly palliative effect, checking the discharge and fœtor and relieving the pain. Complete recovery from the disease was, of course, not to be expected, but in inoperable

cases the patient's general condition improved to some extent and there was obvious mitigation of the symptoms.

*A Colony for Children Suffering from Whooping-cough.*

A limited liability company was recently formed for the purpose of establishing on the shore of the Baltic a health resort for children suffering from whooping-cough. Hitherto those children when a change of air had been prescribed for them by a medical man were usually taken to some place on the seaside or in the mountains, where they associated with healthy children, who were thereby liable to be infected; it moreover often happened that the patients were requested by the hotel proprietors to take their departure as soon as the nature of the disease was known. In order to avoid these risks and inconveniences the above mentioned company undertakes to form a kind of colony where only families with children suffering from the disease will stay. The establishment will include a number of isolated houses, each for one family; playgrounds and other opportunities for recreation will be provided and there will be a large separate kitchen in which all the food will be prepared. The colony is at some distance from other habitations as well as from any frequented main road. It is, of course, intended for well-to-do people only, but if the undertaking proves successful similar institutions for children of the humbler classes will no doubt be established by some of the municipal authorities.

*Radium in the Treatment of Gout and Rheumatism.*

In a communication to the Berlin Medical Society Professor His not long ago gave an account of the results which he had obtained in the treatment of gout and rheumatism by radium. He said that of 100 patients who had been under his care suffering from chronic rheumatism 50 per cent. showed an obvious amelioration, a great number showed a remarkable improvement, and five recovered completely. All the cases were very severe and had been treated without success by other methods. The success obtained in 28 cases of gout was still more striking, as only four showed no change, whilst of the remaining 24 some were considerably improved and some recovered completely. The differential diagnosis between chronic rheumatism and genuine gout was sometimes rather difficult; he maintained it was essential to examine the blood as to the presence of uric acid. In cases of real gout the uric acid generally disappeared under the radium treatment in a period varying from a few days to several weeks, its gradual diminution being accompanied by an improvement in the clinical symptoms. With regard to the administration of radium Professor His recommended the inhalation of radium emanation, a procedure in which the patients must spend two hours daily in an "emanatorium." The administration of a fluid containing radium by injections made in the neighbourhood of the affected joints was also very efficacious. Radium influenced metabolism and, moreover, made the ferments of the organism active. It was, of course, not a panacea for every case of gout; in inveterate cases accompanied by osseous ankylosis of the joints success could not be expected. The dose must be graduated according to the state of the individual patient. In the discussion Dr. Fürstenberg called attention to the soporific action of radium. Dr. Gudzent said that after the use of radium some patients fell asleep, but others on the contrary became excited.

## BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

*The Limitation of Families and the Superior Hygienic Committee.*

THE census held in the first two weeks of January, 1911, has had the unexpected result of showing that the increase of the population is far from being satisfactory. In large towns the general increase is not more than from 10 to 15 per cent., whilst in small provincial towns it varies from 3 to 5 per cent., and there are villages the inhabitants of which have even decreased in number during the last decade in consequence of emigration. This state of affairs has naturally caused some uneasiness among those who regard increase of population as an indication of national prosperity. The first and most obvious cause of the diminished rate of increase is emigration. Although multitudes of emigrants come back penniless from America, hundreds and hundreds continue to ask for emigration passports to that country. Another factor in the question is the dangerous spread of the "only child" system, which is threatening to place us in a position similar to that of France some 10 or 15 years ago. It seems strange that the hygienic authorities of the State should be so apathetic as they are in regard to this problem, for it might be possible to convince some delinquents of the error of their ways, and popular lectures on the perils of artificially induced abortion might act as a deterrent. In some parts of the country, as, for instance, in the county of Baranya, ordinary peasant women can manipulate the uterine sound (or a catheter) for the purpose in question with admirable skill, observing all the rules of antisepsis in their work. The police are aware of these facts, but can do nothing because offenders evade detection by performing these operations mostly in the second or third month of pregnancy, before the woman's condition has become noticeable. Hungary being an agricultural country the shortage of able-bodied men is especially felt by farmers and landed proprietors—so much so indeed that last summer in some parts of the country harvesting had to be put off from week to week for want of hands. This fact induced the board of the "National Hungarian Agricultural Society" to ask the Government to take some measures against this national peril which in popular language is called "egyke" (onelet, only child). They were particularly desirous that the Government should prohibit the sale of articles for the mechanical prevention of conception (*condomes*), which, according to the board, are mostly to blame for the prevalence of the only child system. The question being to some extent connected with public hygiene the Government requested the Superior Hygienic Committee to give an opinion thereon. The text of this opinion was compiled by Dr. W. Tauffer, professor of gynæcology at the University of Budapest, who acknowledged that the law relating to artificially induced abortion is rather lax, and promised that the committee will also see that in future the medical students in the University and the midwives in the midwifery schools shall be instructed to enlighten their patients as to the dangers and evil consequences of artificial miscarriage. In discussing the general subject of the limitation of families Professor Tauffer said that, in his opinion, the increase of population, looking at it from a hygienic point of view, was a question of food-supply only, for the propagating rate of mankind, when left to itself, tended to rapid increase, but the supply of food was limited and increased but slowly. In consequence of these views being generally accepted heads of families were now becoming anxious to limit the number of their descendants. Professor Tauffer further remarked that criticism of the means with which ministers of religion, moralists, politicians, whether military or agrarian, and capitalists tried to check the spread of this habit was not the task of the Superior Hygienic Committee. The publication of Professor Tauffer's opinions gave rise to acrimonious discussions in the newspapers, the agrarian party being prominent in expressing their dissatisfaction with his views, and in bringing this to his notice they did not select the politest phrases. Even in the dignified *Fiqyelo* there is a long article wherein Professor Tauffer's opinion is discredited and his teaching condemned. Count Apponyi, the late Minister for Public Instruction, has challenged the advocates of restriction to meet him in a discussion on this question, but Professor Tauffer has told an interviewer that he would not enter into a controversy of that kind with Count Apponyi, who is not a medical man. This agitation has induced Francis Herczegh, a sympathiser with the agrarian party and the foremost Hungarian dramatist and novelist, to write a long article with the title "Marginal Notes to the Only-child Question," wherein he seeks to prove the errors of Professor Tauffer's opinion. In the concluding part of his article he says that the essential condition of the medical calling is the defence of the principles of life, and that only on such grounds could medical men be entrusted as they are with powers greater than those of any other human authority. After denouncing the attitude of the Superior Hygienic Committee he expresses a hope that the Hungarian medical men will not be influenced by that pernicious example, but will follow the path in which they are led by their knowledge, conscience, and patriotism. In reply to this critic Professor Tauffer has

published a rejoinder in which he says that the physical well-being of the people, their education, the increase of public wealth, the improvement of the hygienic administration of the country, the inspection and disciplining of individuals dealing with obstetrics, the directing and controlling of the nursing hygiene of infants,—these are some of the things most urgently required to be done, and as a result of them a numerical increase of the population of the country may be expected, even if the births do not increase in the same proportion.

## SWITZERLAND.

(FROM OUR OWN CORRESPONDENT.)

*Successful Removal of a Subdural Tumour of the Spinal Tract.*

Dr. O. Veragut, *privat-docent* on neurology in Zürich, and Dr. H. Brun, surgeon in Lucerne, report on the following interesting case in the *Korrespondenzblatt für Schweizer Aerzte* of Nov. 20th and Dec. 1st, 1910. The patient was a man, aged 32 years, a widower, with one healthy boy, aged 3 years; his wife died from consumption and one of his brothers from tuberculous hip disease. Four years ago he was under treatment for consumption, but was afterwards able to continue his work. In December, 1909, he complained of stiffness and pain in the nape of the neck and left shoulder; in January, 1910, of numbness of the left arm which disappeared again, but afterwards the arm felt weaker. Later the right also felt numb and weak. He felt himself growing gradually weaker. At the end of January a burning sensation was felt in the nape of the neck and a burning sensation round the navel, also drawing pains in the left leg. The apex of the left lung was retracted and dull to percussion; catarrhal sounds were heard; tubercle bacilli in small quantities were found in the sputum. The patient held his head forward in a stiff manner; on rotation he complained of pain. Pressure on the head and spine was painless. Roentgen ray pictures showed a normal condition. There was hypæsthesia over the left shoulder. Passive movements of the left thumb and fingers were not perceived if the patient shut his eyes; he could not distinguish small objects placed in his left hand. There was contraction of the pectoral and teretes muscles. Abduction of the left arm was deficient; adduction with the elbow bent was less energetic than on the right side. Spontaneous fibrillary movement was seen in the deltoid and triceps muscles. The muscular power of the upper arm was considerably diminished. Spontaneous flexion and extension of the arm at the elbow-joint were executed very incompletely and with difficulty. The left leg trembled in the standing position and there was slight spasm in walking. The faradic and galvanic reaction of deficient muscles was normal. The triceps reflex on the left side was increased, as were also the periosteal and tendon reflexes. Slight pressure in the lacertus fibrosus of the upper arm on the left side caused rotatory clonus (clonic rotatory contractions) which ceased with the pressure. This clonus could only be produced in half-abduction of the upper arm and rectangular flexion of the elbow. The patellar reflexes on both sides were increased and there was clonic foot spasm. The Babinski sign and Oppenheim sign were present on the left side only. A diagnosis of tumour in the spinal cord compressing it at the level of the fourth cervical segment was made. The examination of five cubic centimetres of cerebro-spinal fluid proved negative. (Hygiene Institute of Zürich: Professor Silberschmid.) By Feb. 17th hypæsthesia over the left shoulder was more complete. There was reduced sensitiveness of the whole right side from the fourth cervical segment downward, but no feeling of vibration (tuning fork), except in the shoulder on the right side. On the left side this was present, and was only absent round the patella and on the shoulder. Astereognosis was total on the left side, partial on the right. The left arm could only be moved at the finger-joints. Passive movements were resisted. The right arm had less power. The left leg could only be slightly moved at the hip and knee. The power of the right leg was reduced. The patient walked like a case of spastic hemiplegia. Shortness of breath, due to paresis of the left phrenic nerve, was present, corroborated by Roentgen ray examination; respirations 27 per minute. As regards the left arm, the triceps, periosteal, and tendon reflexes were increased. The rotatory clonic spasm supervened in every position of the arm, and on slight pressure, also on tickling the left foot. The Babinski sign was present on both sides, and Oppenheim's sign only on the left side. The cremasteric reflex was present on the right side. The abdominal reflexes had disappeared. By Feb. 18th the left arm was totally anæsthetic. A diagnosis of a localised meningitis was excluded by the normal condition of the cerebro-spinal fluid. The slow progress of symptoms pointed to a growth of intradural but extra-medullary position, probably a sarcoma or fibro-sarcoma. On Feb. 18th, 1910, under ether narcosis, an operation was performed. The third and fourth spinous processes were removed and the laminæ resected. Hæmorrhage was successfully treated by compression. The dura mater was normal, not thickened, and the subdural cavity was empty. No pulsation of the cord was seen. No tumour. The medulla was slightly thickened over the third segment. Slight injection of the blood-vessels of the pia mater was present. Palpation revealed a greater resistance, pointing to circumscribed intra-medullary tumour. The pia mater was incised and there appeared a small spot 2 millimetres in circumference, the yellow colour of which contrasted with the white nerve substance. A small tumour of the shape of a hazel-nut was peeled out of the medulla like the yelk out of a hard-boiled egg. Scarcely any hæmorrhage occurred. The medulla began to pulsate again. The pia was replaced and the dura carefully sutured with silk. Catgut sutures of soft parts were used and the wound was drained. The tumour weighed 1¼ grammes, = 20 grains. Dimensions, 17 mm. by 11·5 mm. by 9·5 mm. Professor Schmid, of the Pathological Institute of Zürich, found it to be a solitary tubercle with thick elastic capsule. The patient breathed much more freely on recovering from narcosis. After eight hours feeling returned slowly in the left shoulder and arm. The gradual recovery was indicated in the original paper by tabulated reports and numerous diagrams. The patient was discharged on the fifty-sixth day after the operation and began work as a telephone operator. On June 26th he walked four miles as well as a healthy subject, and could lift a chair with his left arm. Slight differences of sensibility in the hand still existed.

Feb. 18th.

## NOTES FROM CHINA.

(FROM OUR OWN CORRESPONDENT.)

*Pneumonic and Septicæmic Plague Epidemic.*

SINCE my last letter events with regard to the spread of this epidemic have marched rapidly, and you will doubtless have read many telegraphic reports in the lay papers. As far as medical records go this epidemic differs in several particulars from previous plague outbreaks—e.g., in its influenza-like infectiousness, its invariably fatal issue, its types, and its incidence. At the present moment it is accounting for 500 deaths daily, and there is no evidence that it is in any way abating.

*History of the epidemic.*—The first signs of plague occurred in the mountainous north-west region of the province of Manchuria. It is said to have originated among the trappers of the *tarabagan*, a small marmot-like rodent, the fur of which is exported to Europe through the station of Manchuria on the Trans-Siberian line. In the summer months the Chinese population of this district, which amounts normally to about 3000, is augmented by some 50,000. In a report of Nov. 24th last it was stated that up to that time 300 persons had been afflicted with plague, not a single one of whom had recovered. It is said that the precautionary and antiplague measures adopted, in the first instance, by the Russian authorities at Manchuria station were of an indifferent order. Be that as it may, by the time the epidemic spread to Harbin the Russians had become alive to the situation and have since done all that was possible. A perusal of the various reports gives ample ground for saying that if the Chinese officials had fallen in with the active measures proposed by the Russians at Harbin the epidemic most probably would have been limited to North Manchuria. But the Chinese prefect (who has since been cashiered) showed himself obstructive and lax to a degree, refusing assistance to the authorities, and allowing the Chinese of the now

thoroughly infected district to use the south bound railway. Fu-Chia-Tien, the Chinatown of Harbin, speedily became a hotbed of plague, and the absence of all restrictions in the way of segregation and quarantine has been followed by the steady spread of the epidemic southwards along the railway. From Changchun it spread to Mukden, and from there south-east to Dalny and south-west to Shan-hai-Kuan, where it passed through the Great Wall into China. Yung-ping-fu, a country town a short distance south of Shan-hai-Kuan (the portal of the Great Wall), became infected, and cases have occurred at Tientsin and Peking. From Tientsin it spread down another railway into the heart of the province of Shantung; and from Peking the infection spread by the Peking-Hankow railway S.S.W. to Paoting-fu and Lung-hua-Tien, on the way to Mid-China. By steamers and native traffic infection was carried across the Gulf of Chihli to Chefoo. And now it remains to be seen if it will maintain its virulence till it reaches the humid zone of Mid-China, with all its teeming millions of people. Up to the time of writing the spread in Tientsin and Peking, two large cities, has been very slow, being limited in each to a mere handful of cases, the contacts from one infection.

*Character of the epidemic.*—Although Chinese figures indicate a certain number of recoveries, all the information given by foreign medical men on the spot points to a mortality of 100 per cent. Rats and fleas do not come into the question as propagators; there has been no noticeable mortality among the former. The transmission has been, like influenza, from man to man, and by direct contact with excretions, or indirectly through the air by the breath and moist particles a few yards round the patient. The majority (about 90 per cent.) of the cases have been of the pneumonic variety, the rest septicæmic plague. The following extract from a letter to me from Dr. W. H. Graham Aspland, now on plague duty at Harbin, gives an idea of the conditions there: "Daily mortality during past week 160; about 40 to 60 die in our hospitals, the remainder picked up by our sanitary men in the streets. In the Russian quarter 40 to 50 deaths daily. Duration of disease after becoming suspects is 2 hours to 2 days. All pneumonic and septicæmic cases with temperature 104° are found going about the streets and declare they have no sickness. Three hours after they are dead. It is simply incredible. Such a condition of life and death is unparalleled in its severity." Except for the deaths of two European medical men and 25 Russians at Harbin (out of a population of 30,000 Russians) the epidemic has been confined to the Chinese coolie classes. So far not a single death has been noted among the Japanese, of whom there are thousands in Manchuria, many living among the Chinese under very similar conditions—the only difference being that they are a cleaner race. In Fu-Chia-Tien—Chinese Harbin—the reduction in population, according to Chinese official estimates, from plague and departures in consequence of it, is from 40,000 to 15,000. It is impossible for anyone to give figures or say what dimensions the epidemic has assumed, owing to the native habit of concealment, against which the plague officials are unable to fight and before which all attempts at obtaining reliable statistics fail lamentably. The mortality rate may be taken at 99–100 per cent.

*Local conditions.*—Owing to severe cold in Manchuria the populace remain indoors as much as possible, and in small unventilated rooms which are usually overcrowded. At night they sleep in rows on "k'angs"—raised mud platforms occupying from three- to four-fifths of the sleeping-room. Wrapping themselves in dirty furs and wadded coverlets, four to six people lie together in a confined, close atmosphere that most Europeans would find insupportable. The sanitary conditions of towns in Manchuria are notoriously bad, and the soil is impregnated with filth and unremoved garbage.

*Manner of spread.*—This is mainly due to the railway (the Imperial Railway of North China). Though the necessary quarantine and inspection measures were not put into force till many people had come through from the infected area, the railway traffic may now be said to be under proper supervision. Foreign medical men are in charge of all the main stations, and by order of the Prince Regent all traffic has been entirely suspended from Mukden in Central Manchuria to the Great Wall. But this has been only a part of the battle. Finding the trains stopped, the Chinese took to the road. Manchuria is invaded every year by thousands of coolies and agricultural labourers from the large provinces of Shantung and Chihli, who go north to earn the high wages prevalent there. With the approach of the Chinese New Year they return in legions, keen to be home for their great annual festival. They will go through fire and water to get back, and it is to such that practically all the cases south of the Great Wall are due. If stopped travelling by train, they tramp the distance by roads—on which no adequate precautions against infection have been taken—and nothing short of the most drastic measures will keep them back. To prevent this flood of coolies pouring into Dairen, the port from which they cross into Shantung, the Japanese have stretched a military cordon across the neck of the peninsula by Kiuchow, and are threatening to strengthen this cordon with a live (electric) wire fence.

In the beginning of January the Imperial Government sent Dr. J. G. Gibb of the Union Medical College to help Dr. Gnoh Lean Tuck at Harbin (to whom I referred in my last letter). Shortly after this Dr. Mesny, the French medical man, became infected while visiting the Russian Hospital and died two days later from pneumonic plague. Since then Dr. Aspland and Dr. J. M. Stenhouse, also of the Union Medical College, have gone up on behalf of the Imperial Government and have been doing all they can to fight the epidemic. At every station down the line medical missionaries have come forward in the most gallant way and borne the brunt in combating the most appalling conditions. At Mukden Dr. A. F. Jackson, of the Scotch Presbyterian Mission, has succumbed to plague, as well as three trained Chinese medical men. The medical profession at the present moment, by these sacrifices and by the number of willing volunteer practitioners, stands higher in the estimation of the Chinese Government than it ever did before. The struggle has been almost entirely in the hands of medical missionaries. If it were not for them China would have to meet this epidemic with a few foreign-trained Chinese medical men of little experience, and lacking in the necessary foresight for preventive measures. The Central Government has been fortunate in having an able and enlightened official at the head of plague affairs. The Honourable Saoke A. Sze (an American M.A.) has from the beginning taken a wide view of the whole question, and if only his orders had been carried out by local officials it is probable that many lives would have been spared. Mr. Sze has concerted with foreign medical men, followed their advice, and by dint of hard work has got quarantine stations established and much preventive work put in hand. The local officials in Manchuria have not only remained apathetic and indifferent but have consistently maintained their dislike and disregard of anything savouring of foreign intervention, even though obviously in their own interests. The Chinese Government has acceded to the request of the Russian Government to appoint an international commission of plague experts from certain Powers. It is doubtful if there are any experts available who can come with an experience gained from similar epidemics, for the local conditions differ very much from those of bubonic plague. No doubt such a commission will be of value later, but for the present there is dire need of foreign medical men at the various stricken towns. The Government offers all local travelling expenses, 300 taels a month (a tael is worth 2*s.* 9*d.*), and an indemnity in case of death of 10,000 taels, to any medical man who may volunteer to help.

*Inoculation.*—It is too early yet to give figures of the value of Haffkine's prophylactic vaccine. I am at present endeavouring to gather information on this point. Medical advices from Harbin have not spoken favourably of Yersin's serum, though they incline to think favourably of Haffkine's vaccine. There is ample scope for bacteriological work, as it is increasingly felt that the difference in type of the epidemic from those recorded elsewhere calls for the manufacture of vaccine on the spot from the local bacillus.

Peking, Jan. 30th.

ROYAL SOCIETY OF MEDICINE: BALNEOLOGICAL AND CLIMATOLOGICAL SECTION.—After the meeting of the section on Wednesday next, as announced in the weekly diary of events, the members will dine together at 7 P.M. at Pagani's Restaurant, Great Portland-street, W. The charge for the dinner is 3*s.* 6*d.*, and members may bring their friends. Dr. A. Manuel, 14, Clarges-street, Mayfair, London, W., would be glad to receive names of those intending to dine.

# Obituary.

## JAMES EDMUNDS, M.D. ST. AND., M.R.C.P. LOND., M.R.C.S. ENG.

THE death of Dr. James Edmunds, consulting physician to the London Temperance Hospital, is announced to have taken place on Feb. 16th at Brighton, where he had lived in retirement for some years past. He was born in 1832, and was the eldest son of the Rev. James Edmunds, an independent minister working among the people in the East-End of London. He received his medical education at the London Hospital, where he gained many distinctions, and qualified M.R.C.S. Eng. and L.S.A. in 1854. He took the degree of M.D. of the University of St. Andrews in 1862, and became a Member of the Royal College of Physicians in 1874. He was for 27 years medical officer of health and public analyst of the parish of St. James's, Westminster, and for seven years medical officer of the H division of the Metropolitan Police. After practising in the City of London for some years he interested himself in the question of the use of alcohol in disease, and wrote various papers on the Physiological Influence of Alcohol. He was one of the founders of the British Medical Temperance Association, and its president from 1876–79, and one of the founders of the London Temperance Hospital and its senior physician. He associated himself intimately with Cardinal Manning in the foundation of the Red Cross Temperance Society and with Canon Fleming in the Church of England Temperance and General Benevolent Society. A temperance advocate of great force and earnestness, Dr. Edmunds was not a fanatic, and his contributions to the literature of this subject were of a progressive and enlightening character. Dr. Edmunds was also a reformer in sanitation. He was cholera medical officer at Newcastle and Dundee in 1853, and contributed the article on the Chemical Analysis of Drinking Water in Sutton's "Volumetric Analysis." Another sphere of action in which Dr. Edmunds was a pioneer was the medical education of women. He founded a society called the Female Medical Society, which was merged afterwards in the London School of Medicine for Women, but as he was not in favour of carrying the medical education of women to the point of qualification and registration as medical practitioners he soon retired from his connexion with the movement.

Amongst his contributions to medical journals should be mentioned the article "Will-making in Aphasic Paralysis," published in the *British Medical Journal* in 1900. He then described the case of a lady, 60 years of age, who suffered from partial right-sided hemiplegia and motor aphasia, with agraphia and word-deafness, though the visual speech centre was unaffected, and who desired to make her will. Dr. Edmunds and Mr. Samuel Garrett, the lady's solicitor, devised a method for ascertaining the wishes of the testatrix by means of printed cards. The will was proved in due course in solemn form, the President of the Probate Court signifying his approval of the method adopted.

Dr. Edmunds was a frequent contributor to the *English Mechanic and World of Science* on all sorts of practical scientific subjects. His modification of Wenham's paraboloid illuminator for the microscope, by cutting the top off flat and fixing it to the slide by a drop of glycerine, thereby rendering it an immersion paraboloid, giving a dark background and luminous object, was described and figured in the same newspaper more than 20 years ago. Quite recently the same principle has been applied to the examination of bacteria and protozoa, with very gratifying results.

Dr. Edmunds leaves a widow, three sons (two of whom are members of the medical profession), and a married daughter.

## GIUSEPPE MYA.

PÆDIATRY has just lost one of its ablest promoters and masters in Dr. Giuseppe Mya, who held the chair set apart for that subject in the Florentine school.

Born at Turin on Sept. 25th, 1857, he became a student of medicine at the local university, and after passing through the curriculum with distinction he took his degree in July, 1881, as Doctor in Surgery and Medicine. Nine years of clinical experience in the Subalpine Hospital evoked his special aptitude in diagnosis and treatment, and in 1890 he was nominated Professore Straordinario in special medical pathology in the University of Siena, adding to his duties those of the chair of Propedeutica Clinica Medica in the same seat of learning. In 1891 he was called to Florence to act as professor of clinical pathology at the Istituto dei Studi Superiori, a post in which he acquired an honourable name both as teacher and consultant. Devoting himself to the diseases of children as a specialty, he rapidly became an authority in that branch of the healing art, attracting to his clinique many students from other schools desirous of perfecting themselves in the diagnosis and treatment of such ailments. In 1899 an invitation from the University of Naples to fill the chair of special medical pathology had many temptations for him, an increase of salary included, but he chose to stay in Florence, which he had made a centre of instruction in his favourite department. In the following year he founded the "Clinica Pediatrica" in the Meyer Hospital, and there he did his most effective work, in diagnosis, therapeutics, and instruction. By this time his pupils had become as numerous as they were enthusiastic, and it is due to him that Italy has of late years made such notable progress in circumscribing the area of infantile disease and the mortality caused by it.

For the last ten years he was in much request as a consulting physician in maladies of the adult, numbering in his *clientèle* many of the foreign residents in the Tuscan capital, and among these not a few of the English-speaking world. His kindly conciliatory address and his conversational charm contributed with his undoubted skill and marked success in practice to ensure his acceptance as a consultant, and to maintain him as the friend in circles where he had won his way as the physician. His contributions to medical literature were as valuable as they were numerous and varied. For special notice may be mentioned his treatise on the "Ittirizie" (the several forms of icterus); on the "Rigenerazione Sanguigna nelle Anemie da Distruzione Globulare"; on "Infantile Splenic Anæmia"; "Sulla Patologia del Rene e delle Vie Urinarie"; "Sul Valore Diagnostico e Curativo della Puntura Lombare"; and, not to mention a highly original and practically useful series of studies on meningitis, his exhaustive and still authoritative monograph on "The Causes and Remedies of Italy's High Infantile Mortality." It is in this field, as already indicated, that his chief professional interest lay and in which he reaped the most enduring reward—endearing himself to innumerable families by his opportune and happy intervention in cases which seemed to baffle every diagnosis less prompt than his own.

As a citizen he took part in municipal affairs, professionally as well as in the council chamber, again with a fertility of resource which seldom failed to solve the difficulty of the hour. But the life he led as clinical worker and as active practitioner proved too much for his strength, and it was foreseen that any illness contracted in his later years must have found him an easy victim. The visitation of influenza under which Florence as well as Rome has been adding to its sick list and death-rate made many calls on his time and strength. He fell ill on Feb. 4th, and after a brief struggle with the malady succumbed quite suddenly on Feb. 5th.

## CHARLES ALEXANDER MACMUNN, M.A., M.D. DUB., F.C.S., F.R.M.S., J.P., V.D.

THE death is announced of Dr. C. A. MacMunn of Wolverhampton. Dr. MacMunn was born in County Sligo in 1852, the son of Dr. James MacMunn. He received his medical education at Trinity College, Dublin, where he graduated M.B. in 1872, taking also the diploma L.R.C.S. Irel. and L.M. At the time of his death he was consulting physician to the Royal Orphanage, Wolverhampton, having retired from the position of pathologist and physician to the General Hospital, Wolverhampton. His contributions to science were many and varied. He was the author of volumes entitled "Clinical Chemistry of Urine" and "The Spectroscope in Medicine," and at the time of his death was engaged upon "The Outlines of Clinical Chemistry," which was nearing completion. He made numerous researches in and wrote several papers on physiological chemistry and animal pigments, published in the Transactions of the Royal Society and other scientific societies. He was also a contributor to the "Encyclopædia Britannica" and the author of articles in Quain's "Dictionary of Medicine." He was administrative

medical officer of the North Midland District Territorial Force, a keen soldier, and on the outbreak of the South African war he went out with the special medical staff, was mentioned in despatches, and received decorations for service. He was appointed by Lord Roberts as staff officer on the Commission which inquired into the administration of the medical service during the war. He was a magistrate for Staffordshire and life governor of the University of Birmingham. For many years he had a large practice in Wolverhampton and district until his failing health forced him to relinquish it and retire. Dr. MacMunn's second wife, who survives him, is a sister of the late Captain Webb, the famous swimmer.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Gustav Braun, formerly professor of midwifery in the University of Vienna and director of the Midwives' School. He was a younger brother of the eminent gynæcologist, Professor Carl Braun von Fernwald, and, like him, published numerous works on midwifery and gynæcology. Dr. Bohr, professor of physiology in the University of Copenhagen. Dr. C. Van Cauwenberghe, professor of midwifery and gynæcology in the University of Ghent. Dr. Guillery, formerly professor of forensic medicine in the University of Brussels. Dr. Giuseppe Albini, formerly professor of physiology in the University of Naples.

# Medical News.

UNIVERSITY OF OXFORD.—In Congregation on Jan. 26th the following degrees were conferred:—

*D.M.*—D. W. Carmalt Jones.
*B.M. and B.Ch.*—G. E. Neligan, G. E. Downs, and A. W. Donaldson.

The following have been elected members of the Board of Faculty of Medicine:—Sir W. S. Church, Bart., Dr. Samuel H. West, Dr. Walter Ramsden, Dr. E. W. Ainley Walker, Dr. William Williams, Dr. H. M. Vernon, Dr. Alexander G. Gibson, and Dr. J. W. Jenkinson.—In accordance with the provisions of the decree of Convocation of Feb. 7th, the examinations for the degree of Bachelor of Medicine will commence in the Examination Schools for the First B.M. on June 15th and for the Second B.M. on June 14th, and not as previously advertised.

ROYAL COLLEGE OF SURGEONS IN IRELAND: DENTAL EXAMINATION.—W. J. Maher and J. L. Moulang have passed the examination of the First Dental Division A. G. Sheedy and A. C. Wiley have passed the examination of the First Dental Division B. P. I. Wigoder has passed the Final Dental Examination and has been admitted a Licentiate in Dental Surgery.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. Max Rothmann, *privat-docent* of Neurology, has been granted the title of Professor.—*Clausenburg:* Dr. Aladár Elfer has been recognised as *privat-docent* of Medical Diagnosis.—*Cologne (Academy of Practical Medicine):* Dr. Stürtz of Metz has been appointed Director of the Tuberculosis Department, in succession to Dr. Dantwiz.—*Gratz:* Dr. Eduard Streissler has been recognised as *privat-docent* of Surgery.—*Kiel:* Dr. F. Klein, of the Chemical and Physiological Institute, has been appointed Extraordinary Professor.—*Königsberg:* Dr. Rhese has been recognised as *privat-docent* of Otiatry and Laryngology.—*Lemberg:* Dr. Ladislaus Mazurkiewicz has been recognised as *privat-docent* of Pharmacognosis.—*Göttingen:* Hitherto there has been no regular Dental Institute, Professor Heitmüller having given instruction to dental students in his own dental surgery. He has now been appointed to a post in Dresden and there is at present no instructor. It is, however, proposed to establish a fully-equipped Dental Institute with the required *docenten*.—*Marburg:* Dr. Martin Benno Schmidt has been offered the chair of Pathological Anatomy in succession to Professor Beneke.—*Rostock:* Dr. F. K. Walter has been recognised as *privat-docent* of Anatomy.—*Vienna:* Dr. Hermann Ulbrich has been recognised as *privat-docent* of Ophthalmology.

LITERARY INTELLIGENCE.—A new series of volumes, under the title of "Notable English Trials," is announced for publication by Messrs. William Hodge and Co., Edinburgh and London. The first volume, entitled "The Trial of the Stauntons," will be issued on March 1st, and will be followed at frequent intervals by volumes dealing with, among others, the trials of Franz Muller, Dr. Palmer, Dr. Lamson, and the Wainwrights. "The Trial of the Stauntons" is edited by Mr. J. B. Atlay. Amongst the editors of the other trials may be mentioned the names of Mr. H. B. Irving, Mr. George H. Knott, Mr. David N. Mackay, and Mr. H. L. Adam. Each volume will be fully illustrated, and the series, when complete, will form a permanent record of the most famous of English trials. The price of each volume will be 5*s.* net.

ST. THOMAS'S HOSPITAL AND THE LAMBETH GUARDIANS.—At a recent inquest held on a woman named Annie Johnson, who died from bronchitis and pneumonia accelerated by starvation and exposure, it was stated that she was found by the police in the street in an exhausted condition and conveyed to St. Thomas's Hospital. After examination by a casualty officer the woman was sent by him in the police ambulance to Lambeth Infirmary, where she died a few hours after admission. The facts were reported to the Lambeth board of guardians, who forwarded them to the hospital authorities. At a meeting of the guardians on Feb. 15th a reply from the secretary of St. Thomas's Hospital was read. It stated that a very full investigation of the circumstances had been held. Had there been a chance of admitting the case it would have been taken in, but the female admitting ward was already overcrowded, and the casualty officer was unwilling to overcrowd it still further by admitting what seemed to him a case for the infirmary. The committee regretted that the case was not taken in if by this means the woman's life could have been saved, but it did not think that this was a case in which any censure was due from it on the action adopted by the medical officer of the hospital. The Rev. Walter Hobbs characterised the reply as extremely satisfactory. Mr. C. W. Baldwin said that what he liked most was the desire of the almoners and the authorities at St. Thomas's Hospital to work harmoniously with the guardians, a view in which the Rev. A. O. Hayes, vice-chairman of the board, acquiesced.

HAPHAZARD MIDWIFERY.—An instance of the fact that, despite the efforts of education authorities and municipal bodies, the old-fashioned type of nurse and midwife still persists was afforded at Wandsworth on Feb. 18th, when Mr. John Troutbeck held an inquiry concerning the death of an infant, aged 19 days, son of a coal porter who lives in Putney Bridge-road. The mother, a woman of more intelligence than is usual among persons in her station, said she was attended in her confinement by a Mrs. West of Sudlow-road, Wandsworth, to whom she paid a fee of 6*s.* Mrs. West on examining the patient recognised that it was a difficult case, for she said she thought it was "all wrong." She also said she thought she could manage, and she proceeded to manage, with the result that the infant's arm was broken. After this accident she said to the mother, "I've broken the child's arm; I couldn't help it." Even then she did not send for a medical man or suggest that one should be called in. When the mother's sister-in-law asked if a medical man should be fetched Mrs. West replied that she knew her business. She bound up the child's arm. The little sufferer was afterwards taken daily to Bolingbroke Hospital till he became too ill. Mrs. West did not attend the inquest. The coroner's officer said she was an old woman. He had found her in bed that morning and she had then told him she was suffering from influenza, but he had been informed that all the Thursday night previous she had been out nursing a patient. Mr. W. G. McDowell, a medical practitioner of Easthill, Wandsworth, who was called in by the parents, gave Mrs. West's account of the matter as he had heard it from Mrs. Smith, the child's mother. Mrs. West called it a breech presentation, though a hand came first, and then a foot after Mrs. West had put the hand back. Subsequently she had great difficulty in getting one of the arms down and in her efforts she broke the limb. Mr. McDowell, in reply to questions, said the case was one which no midwife ought to have undertaken. Trained midwives, in fact, were told that they must not attempt such cases. Dr. L. Freyberger, who made the post-mortem examination, gave the cause of death as heart failure, accelerated by inflammation of the lungs and by the injury to the arm. He agreed that a case of this kind was far beyond the skill of a midwife. The coroner, addressing the jury, said midwives were allowed to practise under very

stringent conditions, one of which was that they should not conduct a difficult case without professional assistance. It would be going too far to say Mrs. West was guilty of manslaughter. She was obviously incompetent to take the case and she caused the injury to the arm, but there was no question of maliciousness. He suggested that the jury should return a verdict in accordance with the medical evidence. The jury adopted this suggestion, and in addition they censured Mrs. West. An official from the London County Council said that the facts would be placed before the committee and there might be further proceedings.

A MEDICAL MAN REWARDED FROM THE CARNEGIE FUND.—At the Thames police court the magistrate, Mr. Dickinson, presented on Feb. 18th the awards made from the Carnegie Heroes Fund to Mr. Nelson Johnstone, Mr. F. Gascoyne, and Mr. F. Levy, in recognition of their conduct in assisting in the removal of Detective-Sergeant Leeson after he had been shot in the early stages of the "Sidney-street Siege." Mr. Johnstone is the medical man who, when summoned by Mr. Levy to the side of the wounded sergeant, made his way to the scene, partially clad, over the roofs of several houses, tended his patient under a heavy fire of pistol-shots from No. 100, Sidney-street, and was himself grazed by a bullet during one of the attempts made to carry the officer to a place of safety. Addressing Mr. Johnstone, to whom he presented a medallion and a cheque for £10, Mr. Dickinson said: "You are a member of a profession which has ever been associated with deeds of heroism and courage and self-sacrifice. Whether those deeds are performed in the pursuit of scientific motives or the amelioration of the sufferings of humanity, or in the plague-stricken districts of Northern China or in the bullet-swept streets of East London, they are equally brave. You yourself have high ideals, evidently, and on Jan. 3rd they moved you to make a heroic endeavour to save the life of a sorely wounded man, and you were willing to imperil and to sacrifice, if necessary, your life in pursuit of those ideals. I congratulate you upon your bravery, and am glad it has fallen to my lot to present you with this token of grateful appreciation." The congratulation and appreciation expressed by the learned magistrate will be heartily echoed by Mr. Johnstone's colleagues in the profession, the credit of which he has so worthily upheld.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—The dinner given by this society on Wednesday, Feb. 22nd, at the Hotel Great Central, the President, Dr. Phineas Abraham, being in the chair, was well attended. The President was supported by Sir James Porter, K.C.B., Medical Director-General of the Navy; Sir Henry Morris, President of the Royal Society of Medicine; Dr. Charters J. Symonds, President of the Medical Society of London; and Mr. Ernest Lane, President of the Harveian Society. After the usual loyal toasts, the toast of the "Imperial Forces" was proposed by Mr. McAdam Eccles and responded to by Sir James Porter, who pleaded for encouragement and support for Mr. Haldane in the present military organisation, which was the last word before conscription. The speaker expressed his own dislike of the idea of conscription, which did not, however, arouse any enthusiasm in his audience; but when he dilated later on the advantages of conscription his remarks were received with applause. Mr. Charters Symonds, in toasting the West London Medico-Chirurgical Society and the West London Hospital, took issue with those who stayed away from meetings and contented themselves with reading the papers afterwards. He insisted on the importance of the personal element. He eulogised the great work of the Cavendish lectures and congratulated the society on their forthcoming lecturer. Other toasts were "Kindred Societies," proposed by Dr. Barry Ball, responded to with considerable humour by Mr. Ernest Lane; "The Guests," by Lieutenant-Colonel Wilson, C.B., responded to by Sir Frederick Eve and Mr. Mostyn Pigott; and "The Chairman," by Dr. Arthur Saunders. Mr. James Davis, Mr. Edgar Coyle, Mr. Charles Collette, Mr. Stuart Debnam, and Mr. John Ivimey contributed to the entertainment of the evening with songs.

THE NATIONAL COUNCIL OF TRAINED NURSES OF GREAT BRITAIN AND IRELAND.—On Feb. 18th a Pageant and Masque took place at the Connaught Rooms, Great Queen-street, London, in support of the "Bill for the State Registration of Trained Nurses." The play, designed by Mrs. Bedford Fenwick, and the words for which were written by Miss M. Mallett, portrayed the Evolution of Trained Nursing and the Right of Life to Health. There was a very large attendance of nurses, medical men, and others interested in furthering the reform which it is hoped that State registration will bring about. The pageant opened with a procession of Immortals headed by Hygeia, impersonated by Miss Irene Fergusson. She was attended by the Four Elements, and followed by the Sprites of Nursing and Science attended by their attributes. After these came a procession of saintly women and women of the nursing religious orders of the centuries from Phœbe of Cenchrea of the first century to Elizabeth Fry of the nineteenth. The procession closed with a banner on which was inscribed the name of Florence Nightingale. The third procession was of hospital matrons and the fourth of nurses past and present. Outstanding figures in the procession were "Sairey Gamp," and a male plague attendant whose "beak" respirator gave a grotesque appearance to the face. The last procession, representing Bills, Acts, Societies, and the Nursing Press, was intended to clinch the argument in favour of State registration, and its arrival was greeted with loud applause. The words of the masque, consisting of prologue, petitions, and epilogue, reach a degree of excellence upon which the writer is to be congratulated, as are also those who took part in the production and arrangement of the pageant.

# Parliamentary Intelligence.

## NOTES ON CURRENT TOPICS.

*Public Health (Ireland) Bill.*

THE Public Health (Ireland) Bill, which has been introduced in the House of Commons by Captain O'NEILL, deals with the sale of meat in urban districts. The principal clause provides that subject to the approval of the Local Government Board, Ireland, any urban council in Ireland may make by-laws with respect to the conduct and management of any abattoir provided by them, and may prohibit within the urban district the sale of any meat otherwise than subject to such regulations as to inspection and otherwise as may be fixed by the urban council in such by-laws. The Bill has been read a first time. Captain O'NEILL, in bringing forward the measure, has the support of Mr. HUGH BARRIE, Mr. MOONEY, Mr. STEPHEN GWYNN, Mr. CHARLES CRAIG, and Mr. EUGENE CREAN.

## HOUSE OF LORDS.

TUESDAY, FEB. 21ST.

*Asylum Officers' Superannuation.*

Lord MONKBRETTON asked His Majesty's Government whether the opinion of the law officers of the Crown had been taken on any question relating to the administration of the Asylums Officers' Superannuation Act, 1909, and whether His Majesty's Government would make any statement on the subject.—Earl BEAUCHAMP replied: The opinion of the law officers of the Crown is being taken by the Home Office with reference to several questions which have arisen under the Asylums Officers' Superannuation Act, 1909, in connexion with appeals to the Secretary of State under Section 15 of the Act by officers and servants of certain asylums. The law officers are being asked by the Home Secretary to advise as to the extent of the Secretary of State's jurisdiction to determine disputes as to the right to superannuation allowance or as to the amount of such allowance, and generally as to the circumstances in which there is any appeal from the decision of a visiting committee under the Act. When the opinion of the law officers is received the effect of it will be made known to visiting committees and others who may be concerned. The Local Government Board has already obtained from the law officers an opinion as to the proper construction to be placed on Section 12 of the Act with reference to the fund out of which superannuation allowances and gratuities are to be paid, and the effect of this opinion is being communicated in a circular letter to the visiting committees of asylums in England and Wales.

## HOUSE OF COMMONS.

WEDNESDAY, FEB. 15TH.

*Poor Relief and Medical Certificates.*

Mr. GOULDING asked the President of the Local Government Board whether the latest official declaration of policy from his department with regard to relief to the respectable aged was the circular of the President of August 4th, 1900, printed in the thirtieth annual report, in which it was laid down that such persons were not to be urged to enter the workhouse at all, unless from actual infirmity, &c., but that, irrespective of any medical certificate, adequate outdoor relief should be granted to them; whether it was customary in accordance with this circular in most unions to grant, without any medical certificate and irrespective of any specific infirmity, outdoor relief to such deserving aged persons as were not entitled to old-age pensions; and whether the draft order as to out-relief, the issue of which was under consideration, would prohibit such outdoor relief in respect merely of old age. The honourable Member also asked whether the right honourable gentleman was aware that the effect of the proposed Outdoor Relief Order would be to transfer the discretion as to the grant of outdoor relief to aged persons from the guardians to the medical officer, and to make it dependent on

his giving a certificate that the aged person was suffering from some specific disease; and whether, in view of such a marked reversal of policy with regard to the deserving aged as compared with that promulgated in the Circular of the Local Government Board of August 4th, 1900, some opportunity would be afforded to the House of Commons to express an opinion on the subject before, by the signing of the proposed new Order, the reversal of policy was carried into effect.—Mr. BURNS (answering both questions) said: I see no reason to dissent from the view that the circular to which the honourable Member refers may be regarded as the latest declaration of the policy of the Local Government Board with regard to the relief of the aged deserving poor, and I am happy to think that the principles there laid down are very generally acted upon by boards of guardians. I may point out that it would not be necessary under the order proposed by the Departmental Committee that a medical officer should certify that an aged person is suffering from some specific disease. A certificate that he is infirm through old age would seem to satisfy the requirements of the Order. The report of the committee is receiving my careful consideration, and I do not propose to take any action upon it at the present moment.

*Rats and Plague.*

Mr. GEORGE ROBERTS asked the President of the Local Government Board whether it had been proved that rats and rabbits in East Anglia were infected with plague bacillus; whether any cases had arisen of such infection being carried to human beings; and whether action was being taken in the matter.—Mr. BURNS answered: A certain number of rats and rabbits in East Anglia have been found to be infected with plague. Four suspected cases of human plague occurred in this area as long ago as September last, but since then no further cases have been observed. Both the local authorities and my department have been taking active measures in the destruction of rats and the investigation of the extent of prevalence of plague amongst rodents and the delimitation of the affected area. Careful watch is also being kept at the ports against the introduction and spread of rat plague.

THURSDAY, FEB. 16TH.

*Precautions Against Plague.*

Mr. GINNELL asked the Secretary of State for Foreign Affairs whether, in view of the danger to unoffending nations from the spread of plague and other preventable diseases, he could see his way to initiating some international movement towards more general observance of the fundamental laws of health and sanitation; and whether British consuls in the principal foreign cities would be asked to report on these subjects and on any precautions now being taken against plague.—Sir EDWARD GREY replied: In 1903 an International Convention was concluded at Paris with the object of applying in a systematic manner the most modern methods of resisting the spread of plague and cholera. His Majesty's Government and most European countries are parties to this convention, and it is open to any country which has not yet adhered to do so at any time. His Majesty's Consular officers abroad always report the appearance of any case of plague, cholera, or yellow fever within their consular district, and the special measures or regulations put into force for the purpose of checking the spread of the disease. During the continuance of any outbreak they are expected to furnish short telegraphic reports at least weekly, showing the number of cases and deaths and the name of the locality affected, and in the case of the present epidemic in Manchuria reports are received almost daily.

*Health Measures in Tientsin.*

Earl WINTERTON asked the right honourable gentleman whether his attention had been called to the protest of the European doctors at Tientsin against the refusal of the foreign consuls to order a sanitary cordon round the European settlement; and whether he would instruct His Majesty's consuls at Tientsin and elsewhere to support the proposal of the foreign medical officers.—Sir EDWARD GREY replied: His Majesty's Government have not so far heard of the protest referred to, but His Majesty's Minister at Peking has been asked by telegraph for a report on the matter.

*Inspector of Lunatics in Ireland.*

In reply to Mr. O'SHAUGHNESSY, Mr. BIRRELL (Chief Secretary to the Lord Lieutenant of Ireland) said: I am well aware and am daily reminded by applicants that the post of inspector of lunatics in Ireland is about to become vacant. In filling the office due regard will be had to the experience of candidates in the management of lunatic asylums and in the treatment of the insane.

*The Midwives Bill.*

Mr. ROBERT HARCOURT asked the President of the Local Government Board whether it had been brought to his notice that there was a growing feeling of opposition to certain provisions in the two successive Midwives Bills introduced by the Government last session, notably the proposed importation for the first time of the machinery of the Poor-law, and the proposed annual renewal of the midwives' registration; whether, with a view to securing the much-needed amendment of the Midwives Act, he would consider the desirability of omitting the provisions to which so much objection was taken; and whether it was intended to introduce any measure on the subject during the present session.—Mr. BURNS answered: I understand that the President of the Council has a Bill ready for introduction from which it is proposed to omit what is known as the annual renewal of midwives' registration. The provisions of the Bill dealing with the payment of medical men called in at the suggestion of midwives were included in the Bill in order to give to medical men some security for their fees, and I should expect that the omission of the provisions would cause disappointment to the medical profession.

Mr. HARCOURT: Is it to be understood that the provisions on the latter point are the same as in the last Bill?

Mr. BURNS: I am not in a position to state that definitely as I am to receive two or three deputations.

*The Royal Commission on Vivisection.*

Mr. IAN MALCOLM asked the Home Secretary when the report of the Royal Commission on Vivisection would be published.—Mr. CHURCHILL answered: I am informed that the report is under consideration, and that although no date can yet be fixed, it is hoped that it may be submitted shortly.

*The Medical Services of India.*

Mr. KELLY asked the Under Secretary of State for India whether the attention of the Secretary of State had been drawn to the resolution passed at the meeting of the Indian National Congress, held at Allahabad on Dec. 28th, 1910, thanking him for his despatch regarding the employment in the superior posts of the civil medical service and requesting the Government of India to take early action in the direction indicated by the Secretary of State for India, and pointing out that in the interests of the public, the medical service, and the profession, as well as in the interests of economy in public expenditure, it was highly desirable that a distinct Indian civil medical service should be constituted, wholly independent of the Indian military medical service; whether he had yet received from the Government of India any report on the various issues concerning the various medical services of India therein referred to; and when did he propose to bring the higher grades of the medical service within reasonably easy access of Indian medical men.—Mr. MONTAGU wrote, in reply: The resolution to which the honourable Member refers has not yet reached the Secretary of State. A despatch on the general question has been received from the Government of India and is under consideration. As regards the final sentence of the honourable Member's question I have nothing to add to the information that I have already given to him.

MONDAY, FEB. 20TH.

*Children in Metropolitan Workhouse Infirmaries.*

Sir ALBERT SPICER asked the President of the Local Government Board whether he would state the number of children at present maintained in the workhouses of the metropolis and the workhouse infirmaries of the metropolis respectively, differentiating between those over and under three years of age.—Mr. BURNS replied: According to the latest returns available there were on July 1st last 21,043 children of all ages in metropolitan Poor-law institutions, of whom 1226 were in workhouses. The number of children under three in infirm wards was 106, and of children over three 34. As to children in other workhouse wards the numbers were, children under three 706 and children over three 380.

*The Water-supplies of England and Wales.*

Mr. REMNANT asked the President of the Local Government Board what steps he proposed to take as a result of the recommendation of the Joint Select Committee on the Water-supplies (Protection) Bill, July 18th, 1910, which agreed with the recommendations of the Royal Commission on Sewage Disposal and of the Royal Commissions on Water-supply of 1869 and on Metropolitan Water-supply of 1893, all of which asserted the principle that there was urgent need for a survey, at once comprehensive and in detail, of the water-supplies and water needs of the country and for the adoption of measures for conserving the supply and disposing of it to the best advantage.—Mr. BURNS answered: In pursuance of an order of the House a return is being prepared relating to the water-supply of every district in England and Wales. This will include information as to the quantities of water now being supplied in each district and as to what further quantities could be supplied from sources at present in use, together with the information as to the character and situation of these sources. I have also obtained the authority of the Treasury to the appointment of a geologist on the staff of my department. I am not without hope of introducing a Bill giving effect to the recommendations of the commission referred to.

*Sleeping Sickness in Rhodesia.*

Mr. NIELD asked the Secretary of State for the Colonies whether large areas of country in Rhodesia had been infected by the malady known as sleeping sickness, and had been declared proscribed areas; whether, in such areas, all cultivation and other work had been suspended; and, if so, what organised effort was being made, and by whom, to stamp out the disease and destroy the cause of infection.—Mr. HARCOURT wrote in reply: Yes, Sir, considerable areas in the Luapula and Luangwas valleys have been declared sleeping sickness areas. I do not think that cultivation is necessarily suspended, though it is necessary sometimes to clear areas near the rivers and the disease is a most serious hindrance to ordinary life and industry. Travelling is forbidden without permits, villages have been removed at the expense of the Government, and the British South Africa Company is taking various other measures in coöperation with the Belgian authorities for dealing with the sickness. The company has strengthened its medical staff and is now sending out a special commission of investigation with a scientific staff and a fully equipped laboratory.

Mr. NIELD also asked the right honourable gentleman whether he had any information as to the destitution caused among the colonists and natives of Rhodesia consequent upon the prevalence of sleeping sickness over large areas, which had been proscribed; whether any, and what, steps had been, or would be, taken to afford relief where necessary, and by whom; and whether there was adequate medical assistance to grapple with the known cases and to enforce precautions against the spread of the disease.—Mr. HARCOURT replied: I am not aware of any special destitution, certainly not among the Europeans, of whom there are very few in North-Eastern Rhodesia. But the prevalence of this terrible disease must necessarily cause suffering among the populations affected. In reply to another question I am indicating the measures taken by the British South Africa Company, which is responsible for the government of the country, to grapple with the disease.

TUESDAY, FEB. 21ST.

*Measles at the Royal Naval Colleges.*

Mr. TYSON WILSON asked the First Lord of the Admiralty whether, in connexion with the outbreak of measles at the Royal Naval Colleges of Dartmouth and Osborne, he could state whether efficient precautions were taken in the making of the uniforms of the naval cadets to prevent the possibility of such outbreaks emanating from that source; whether he was aware that the uniforms of the cadets at the Royal Military Academy were made in Government workshops under strict sanitary conditions; and whether he would inquire as to whether similar precautions were taken in the making of the uniforms of the naval cadets.—Mr. MCKENNA replied: The Admiralty have no reason to suppose that the firms who are employed by parents of naval cadets to make uniforms do not take proper precautions for the protection of their customers, or that infectious disease has ever been introduced into the colleges in the manner suggested.

*Vaccination in the Navy.*

Mr. POINTER asked the First Lord of the Admiralty whether, in view of the fact that the number of small-pox cases in the Navy had been

very small for the last few years, owing to the strict measures of isolation now adopted and the numerous improvements in the general treatment of the men, he could see his way to extend to naval recruits the same liberty of conscience in regard to vaccination as had already been granted to other branches of the Government services.—Mr. MCKENNA wrote in reply: As the danger of the spread of infection is very largely increased by the peculiar conditions of life on board ship, it is not proposed to relax the present regulations with regard to vaccination.

## BOOKS, ETC., RECEIVED.

ARNOLD, EDWARD, London.

Modern Methods of Water Purification. By John Don, F.I.C., A.M.I.Mech.E., and John Chisholm, A.M.I.Mech.E., Engineer and Manager of the Airdrie, Coatbridge, and District Waterworks. Price 15*s.* net.

CASSELL AND COMPANY, LIMITED, London, New York, Toronto, and Melbourne.

A Text-book of Gynæcological Surgery. By Comyns Berkeley, M.A., M.D., B.C. Cantab., F.R.C.P. Lond., M.R.C.S. Eng., and Victor Bonney, M.S., M.D., B.Sc. Lond., F.R.C.S. Eng., M.R.C.P. Lond. Price 25*s.* net.

CHURCHILL, J. AND A., London.

Urine Examination Made Easy. A Plan of Examination with the Common Tests Fully Described. By Thomas Carruthers, M.A., M.B., Ch.B. Second edition. Price 1*s.* 6*d.* net.

Vicious Circles in Disease. By Jamieson B. Hurry, M.A., M.D. Cantab. Price 6*s.* net.

DULAU AND CO., LIMITED, 37, Soho-square, London, W.

University of London. Francis Galton Laboratory for National Eugenics. Eugenics Laboratory Memoirs. XII. Treasury of Human Inheritance. Parts V. and VI. Section XIV. A: Hæmophilia. By William Bulloch, M.D., and Paul Fildes, M.B., B.C. With 17 Plates of Pedigrees and 1 Plate of Illustrations. Plates XXXIV.-L. Plate N. Pedigrees, Figs. 373-607, 493 bis. Price 15*s.* net.

FISCHER, GUSTAV, Jena.

Handbuch der Vergleichenden Physiologie. Herausgegeben von Hans Winterstein in Rostock. Dreizehnte Lieferung. Band II. Physiologie des Stoffwechsels. Physiologie der Zeugung. Erste Hälfte. Price M.5.

FROWDE, HENRY, AND HODDER AND STOUGHTON, London.

Oxford Medical Publications. Cholera and its Treatment. By Leonard Rogers, M.D., F.R.C.P., F.R.C.S., B.S., I.M.S. Price 10*s.* 6*d.* net.

GRIFFIN, CHARLES, AND COMPANY, LIMITED, London.

Modern Methods of Sewage Purification: A Guide for the Designing and Maintenance of Sewage Purification Works. By G. Bertram Kershaw, Consulting Engineer. Price 21*s.* net.

The Liverworts, British and Foreign. By the Right Honourable Sir Edward Fry, G.C.B., with the Assistance of Agnes Fry. Price 2*s.* 6*d.* net.

# Appointments.

*Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to* THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

ALCOCK, G. H., M.R.C.S., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Creech St. Michael District of the county of Somerset.

BEALE, PEYTON T. B., F.R.C.S. Eng., has been appointed Consulting Surgeon to the Great Northern Central Hospital.

BELL, CLIFFORD T., M.B., C.M. Aberd., has been appointed Resident Medical Officer at the Oldmill Poorhouse, Aberdeen.

BRASHER, CHARLES WILLIAM JAMES, M.B., Ch.B. Bristol, L.R.C.P. Lond., M.R.C.S., has been appointed Medical Registrar to the Bristol Royal Infirmary.

CAMPBELL, SYDNEY, M.B., Ch.B. St. And., has been appointed Medical Officer to the Dundee Post-office.

CHAPPLE, HAROLD, B.C. Cantab., M.R.C.S., L.R.C.P. Lond., has been appointed Clinical Assistant to the Chelsea Hospital for Women.

CLARKE, WILLIAM BRUCE, F.R.C.S. Eng., has been appointed one of the Medical Referees under the Workmen's Compensation Act, 1906, for County Court Circuit No. 42.

CUNLIFFE, ERNEST NICHOLSON, M.D. Vict., has been appointed one of the Medical Referees under the Workmen's Compensation Act, 1906, for County Court Circuits Nos. 7 and 8, and to be attached more particularly to Salford and Manchester County Courts.

DAVIDSON, PATRICK MOIR, L.R.C.P. Edin., L.F.P.S. Glasg., has been appointed one of the Medical Referees under the Workmen's Compensation Act, 1906, for County Court Circuit No. 9, and to be attached more particularly to Macclesfield, and Congleton and Sandbach County Courts.

HAY, PERCIVAL J., M.D., Ch.B. Edin., has been appointed one of the Medical Referees under the Workmen's Compensation Act, 1906, for County Court Circuit No. 16, with a view to his being employed in all Ophthalmic Cases which may arise in the Circuit.

HEREFORD, CHARLES FRANCIS ALEXANDER, L.R.C.P. Lond., M.R.C.S., has been appointed Honorary Dental Anæsthetist to the Bristol Royal Infirmary.

JOHNSON, G. W., M.B., B.S., has been appointed House Physician at University College Hospital.

THOMSON, HERBERT CAMPBELL, M.D. Lond., has been appointed one of the Medical Referees under the Workmen's Compensation Act, 1906, for County Court Circuit No. 40.

TUKE, A. L. S., M.B., M.Ch. Edin., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Dunfermline District of the county of Fife.

WILLIAMS, D. LLEWELYN, F.R.C.S. Edin., D.P.H., has been appointed Medical Officer of Health to the Denbigh County Council.

WRIGHT, ANDREW JOHN METFORD, M.B., B.S. Lond., F.R.C.S. Eng., L.R.C.P. Lond., has been appointed Surgical Registrar to the Bristol Royal Infirmary.

# Vacancies.

*For further information regarding each vacancy reference should be made to the advertisement (see Index).*

ABERDEEN ROYAL INFIRMARY.—Assistant Medical Electrician.

ASHTON-UNDER-LYNE UNION WORKHOUSE.—Assistant Medical Officer. Salary £150 per annum, with rations, laundry, and residence.

BIRMINGHAM AND MIDLAND HOSPITAL FOR SKIN AND URINARY DISEASES.—Clinical Assistant for three months. Salary at rate of 52 guineas per annum.

BRIGHTON, SUSSEX COUNTY HOSPITAL.—Assistant House Surgeon, unmarried. Salary £60 per annum, with apartments, board, and laundry.

BURY AND DISTRICT FEVER AND SMALL-POX HOSPITALS AND SANATORIUM FOR CONSUMPTIVES.—Medical Superintendent. Salary £400 per annum.

CANCER HOSPITAL, Fulham-road, London, S.W.—House Surgeon] for six months. Salary £70 per annum.

CARLISLE, CUMBERLAND INFIRMARY.—Resident Medical Officer, as House Physician for first six months and House Surgeon for ensuing six months. Salary at rate of £80 and £100 per annum respectively, with board, lodging, and washing.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park, E.—Pathologist. Salary at rate of 100 guineas per annum.

DERBY, COUNTY BOROUGH OF.—School Medical Officer. Salary £250 per annum.

DUBLIN, ROYAL VICTORIA EYE AND EAR HOSPITAL, Adelaide-road.—House Surgeon. Salary £40 per annum, with board and residence.

DUMFRIES AND GALLOWAY ROYAL INFIRMARY.—Assistant House Surgeon. Salary £55 per annum, with board and washing.

DUMFRIES, COUNTY AND BURGHS OF.—Medical Assistant to Medical Officer of Health and School Medical Officer. Salary £250 per annum.

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Shadwell, E.—House Surgeon. Salary at rate of £75 per annum, with board, residence, and laundry. Also Officer for the Electrical Department.

EDINBURGH ROYAL INFIRMARY.—Superintendent. Salary £600 per annum, with house, coal, and light.

FARRINGDON GENERAL DISPENSARY AND LYING-IN CHARITY, 17, Bartlett's Buildings, Holborn-circus, E.C.—Resident Medical Officer. Salary £100 per annum, with rooms, attendance, fire, &c. Also Honorary Dental Surgeon.

GARTLOCH MENTAL HOSPITAL, near Glasgow.—Resident Assistant Physician. Salary £125 per annum.

HULL ROYAL INFIRMARY.—Assistant House Surgeon. Salary £100 per annum, with board and lodging. Also Casualty House Surgeon for six months. Salary at rate of £60 per annum, with board and lodging.

JERSEY GENERAL DISPENSARY AND INFIRMARY.—Resident Medical Officer, unmarried. Salary £100 per annum, with apartments, board, and attendance.

KING EDWARD VII. MEMORIAL SANATORIUM FOR SHROPSHIRE.—Resident Medical Officer, unmarried. Salary £200 per annum, with board and residence.

LEAMINGTON, WARNEFORD, LEAMINGTON, AND SOUTH WARWICKSHIRE GENERAL HOSPITAL.—Junior Resident Medical Officer. Salary £65 per annum, with board, washing, and apartments.

LEEDS PUBLIC DISPENSARY.—Junior Resident Medical Officer. Salary £100, with board and lodging. Also Honorary Dental Surgeon and Honorary Assistant Dental Surgeon.

LIVERPOOL, ROYAL SOUTHERN HOSPITAL.—Three House Surgeons and Two House Physicians for six months. Salary at rate of £60 per annum, with board and residence.

LLANYBYTHER, CARMARTHENSHIRE, WEST WALES SANATORIUM.—Medical Superintendent. Salary £250 per annum, with board and residence.

LONDON FEVER HOSPITAL, Liverpool-road, Islington, N.—Physician and Assistant Physician.

MAIDSTONE, WEST KENT GENERAL HOSPITAL.—Assistant House Surgeon, unmarried. Salary £80 per annum, with board, residence, &c.

MANCHESTER CHILDREN'S HOSPITAL, Pendlebury, near Manchester.—Resident Medical Officer, unmarried. Salary £90 per annum.

MILLER GENERAL HOSPITAL FOR SOUTH EAST LONDON, Greenwich-road, S.E.—Senior and Junior House Surgeon, each for six months. Salaries £100 and £80 per annum respectively, with board, attendance, and laundry.

NEWCASTLE-UPON-TYNE, UNIVERSITY OF DURHAM COLLEGE OF MEDICINE.—Lecturer on Public Health.

NEW HOSPITAL FOR WOMEN, Euston-road.—Senior Assistant (female) in Out-patient Department.

PLYMOUTH, SOUTH DEVON AND EAST CORNWALL HOSPITAL.—Honorary Anæsthetist.
PORTSMOUTH, ROYAL PORTSMOUTH HOSPITAL.—Assistant House Surgeon. Salary £75 per annum, with board, &c.
ROCHESTER, ST. BARTHOLOMEW'S HOSPITAL.—House Physician. Salary £110 per annum, with board and residence.
ROYAL EAR HOSPITAL, Soho.—Honorary Assistant Anæsthetist.
ROYAL NAVAL MEDICAL SERVICE.—Twelve Commissions.
ST. MARY'S HOSPITAL MEDICAL SCHOOL, Paddington, W.—Lecturer on Anatomy. Salary at rate of £350 per annum.
ST. PANCRAS AND NORTHERN DISPENSARY, 126, Euston-road.—Resident Medical Officer, unmarried. Salary £105 per annum, with residence, attendance, and midwifery fees.
ST. THOMAS'S HOSPITAL.—Obstetric Physician.
SALFORD ROYAL HOSPITAL.—Junior House Surgeon for six months. Salary at rate of £50 per annum, with board and residence.
SCARBOROUGH HOSPITAL AND DISPENSARY.—Junior House Surgeon. Salary £80 per annum, with board, residence, &c.
SHEFFIELD ROYAL HOSPITAL.—Honorary Assistant Ophthalmic Surgeon, Honorary Physician for Skin Diseases, and Honorary Assistant Dental Surgeon.
SHEFFIELD UNIVERSITY.—Demonstrator in Anatomy. Salary £150 per annum.
SOUTHAMPTON, ROYAL SOUTH HANTS AND SOUTHAMPTON HOSPITAL.—House Surgeon. Salary £100 per annum, with rooms, board and washing.
SOUTHPORT INFIRMARY.—Resident Junior House and Visiting Surgeon, unmarried, for six months. Salary £70 per annum, with residence, board, and washing.
STOCKPORT INFIRMARY.—Junior House Surgeon. Salary £80 per annum, with board, washing, and residence. Also Senior House Surgeon. Salary £100 per annum, with board, washing, and residence.
SUNDERLAND INFIRMARY.—Two House Surgeons. Salary £80 per annum, with board, residence, and washing.
TAUNTON UNION, ST. JAMES DISTRICT.—Medical Officer. Salary £85 per annum.
TOWER HAMLETS DISPENSARY, Whitehorse-street, Stepney, E.—Resident Medical Officer. Salary £100 per annum, with apartments, washing, light, and attendance.
UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL.—Second Demonstrator.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—Resident Surgical Officer. Salary £125 per annum, with board, apartments, and laundry.
WORCESTER COUNTY AND CITY ASYLUM, Powick, Worcester.—Third Assistant Medical Officer. Salary £140 and all found.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of a vacancy as Certifying Surgeon under the Factory and Workshop Act at Mold, in the county of Flint.

# Births, Marriages, and Deaths.

## BIRTHS.

HUNTER.—On Feb. 19th, at Normanhurst, Royston Park, Hatch End, the wife of Mark O. Hunter, M.A., M.R.C.S., of a daughter.
PERKINS.—On Feb. 18th, at "Comberton," Tunbridge Wells, to Dr. Philip and Mrs. Perkins, a son.
PHILLIPS.—On Feb. 14th, at Hamilton House, Penge, the wife of Harry Harding Phillips, M.R.C.S., &c., of a son.
PORTEOUS.—On Feb. 18th, the wife of Dr. Porteous, Newbury House, Weston-super-Mare, of a daughter.

## MARRIAGES.

CROMPTON—MAY.—On Feb. 14th, at St. Barnabas, Dulwich, Kenneth Edward Crompton, B.A., M.B., B.C., of Peachland, British Columbia, to Elsie, eldest daughter of Richard J. May, of Pond House, Dulwich.
HATFIELD—JAMES.—On Feb. 16th, at Lewisham, Henry Francis Hatfield, L.R.C.P., M.R.C.S., to Helena Emily James, widow of the late Charles James, and third daughter of Alexander Hunter, L.R.C.S. Edin.

## DEATHS.

BENNETT.—On Feb. 16th, at College House, Hammersmith, W., Charles Henry Bennett, M.D., J.P., late Honorary Surgeon-Major, 3rd City of London R.V.
CURNOCK.—On Feb. 13th, at Kendalcroft, Epping, George Dennis Curnock, L.D.S. Eng.
EDMUNDS.—On Feb. 16th, at Sussex-square, Brighton, James Edmunds, M.D., M.R.C.P., aged 79 years.
MCGEAGH.—On Feb. 17th, at Bournemouth, James P. McGeagh, M.D., the beloved husband of Mary McGeagh, of Bradstone, Branksome-avenue, Bournemouth.
MACMUNN.—On Feb. 18th, at 5, Lonsdale-road, Wolverhampton, Charles Alexander MacMunn, M.A., M.D., V.D., J.P., aged 58 years.

*N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

# Notes, Short Comments, and Answers to Correspondents.

## INEBRIETY.

*S. A.* writes desiring to be referred to one or two authoritative books on inebriety. If our correspondent wants a work dealing specially with the medical aspect of inebriety, he will probably not find anything better in English than the old book by Norman Kerr—"Inebriety or Narcomania" (Lewis, third edition, 1894), despite some teetotal exaggerations. There is no modern book devoted solely to the subject from the point of view of treatment, and we do not think that the articles on it in the medical dictionaries are very satisfactory either. With Kerr's book should be read the text-books on insanity—with special mention of Legrain's article in Hack Tuke's "Dictionary of Psychological Medicine"—and works dealing with particular methods of treatment, such as Milne Bramwell or Tuckey *qud* hypnotism, the annual reports of the Norwood Sanatorium (Dr. F. Hare) as to drug treatment, &c. If, on the other hand, he is interested in the whole question of alcoholism, and wants books on its medico-sociological aspect, we can safely recommend "The Drink Problem," edited by Dr. T. N. Kelynack (Methuen, 1907). There are also some good, perhaps better, foreign books of the same sort—e.g., "Der Alkoholismus," by A. Grotjahn (Leipzig, Wigand, 1898), and the "Traité de l'Alcoolisme" of Triboulet, Mathieu, and Mignot (Paris, C. Naud, 1905). Dr. W. C. Sullivan's volume, "Alcoholism" (Nesbit, 1906) and Dr. Arthur Shadwell's "Drink, Temperance, and Legislation," are valuable studies of the question from the economic side. It is curious with all that is talked and written about the subject it should be so difficult to find a work that is not more or less disfigured by rhetoric or obscured by prejudice.

## THE FEEDING OF INFANTS.

*To the Editor of* THE LANCET.

SIR,—Can any of your readers tell me whether the two-hourly feeding commonly recommended for an infant in the first month or six weeks of life is founded on theory or on the natural demands of a normal infant? I am, Sir, yours faithfully,

Kilbarchan, Renfrewshire, Feb. 13th, 1911. THOS. CARRUTHERS.

*** The recognised method among English-speaking nations of feeding the new-born infant every two hours appears to be founded solely on usage and authority. There appears to be little physiological justification for such a practice, although it has been sanctioned and perpetuated by the writings of the most eminent authorities in this country and in America and by the practical example of the large maternity hospitals in London, Dublin, and in the provinces. Frequent feeding of this character is not practised on the continent. Dr. W. Camerer, writing in the last edition of Pfaundler and Schlossmann, advocates intervals of three and a half hours during the first three months of life, with an extension to four hours as the infant grows older. While in Professor v. Hutinel's text-book on the diseases of children, a work which may be said to be representative of French views on this subject, the intervals recommended for feeding the new born are set at two and a half hours. Dr. A. Czerny of Breslau, one of the greatest of living authorities on infant feeding, says: "The breast-fed should not be fed at all upon the first day of life, and on the following day only three or four times in the 24 hours. Afterwards five or six feedings in the day are sufficient. These directions are not given arbitrarily, nor do they follow any authority, but they are derived from observation of numerous breast-fed children who have had their food when they wanted it, and not according to the advice of a physician." Dr. Czerny is a strong advocate of long intervals between feeding; indeed, he declares in favour of prolonging rather than shortening the intervals. In cases of malnutrition or restlessness he says the minimum interval of feeding should be three hours.—ED. L.

## "STANDARD BREAD."

A CORRESPONDENT points out that the controversy on the relative merits of stone-ground and roller-milled flour, which has been recently revived with some ardour and success, was commenced in THE LANCET 30 years ago. In a letter which was published in this journal on June 10th, 1882, Mr. Stephen Harding Terry, M.I.C.E., referred to the probable future effect of roller milling on the health of the nation, the suggestion to introduce this method being apparently at that time a fresh one. We take one sentence from Mr. Terry's letter, which shows that his predictions and fears were amply justified. "When it is borne in mind," he wrote, "how large a portion of the population of this country (more especially children) live principally on bread, in some form or other, and that whilst growing they require a larger proportion of bone- and tissue-forming material than at a later period, I think the medical and engineering professions will agree with me when I state that the processes involved in the preparation of bread from grain should be such as to

leave in the resulting 'loaf' those elements which entitle it to its ancient name 'the staff of life,' and that the changes in the chemical composition of bread which are likely to follow an extended use of improved mill machinery ('high grinding') are well worthy the attention of medical men." This is an interesting contribution to the history of the roller-mill method of separating flour from the wheat grain.

## ANCIENT DRUG POTS AND PILL SLABS.

AT the sale at Christie's on Feb. 14th of the collection of porcelain and other objects of art formed by the late Sir John Evans, K.C.B., F.R.S., some time president of the Society of Antiquaries and a trustee of the British Museum, the undermentioned lots, in the Lambeth and other pottery sections, were disposed of at the prices indicated:—

A drug pot, painted with a winged mask in blue and the date 1668, and inscribed LEPVLM. WLF (extract of wolf's lungs) 7¼ in. high—6 guineas.

Two drug pots, nearly similar, painted with cherubs and shells in blue, and inscribed THER: LOND (London treacle) and C: CYNOSBA (conserve of the pips of the dog rose), 7¾ in. high—8 guineas.

A drug pot, painted with cupids, shells, and foliage, and inscribed THER: ANDRO (Venice treacle, antidote to poison), formerly the property of Sir A. W. Franks, K.C.B.; and one, with birds and foliage, inscribed V: ÆGYPTIAC (mullein), 8¼ in. high—5½ guineas.

A drug pot, painted with cherubs and foliage, and inscribed PHILº. LONDE, 7¼ in. high, and one, nearly similar, inscribed V. CERAT, 7¼ in high—6 guineas.

A large drug pot, inscribed E. LENITV, 11 in. high, formerly the property of Sir A. W. Franks. K.C.B.; a smaller jar, similarly inscribed, 7 in. high, from the same collection; and a jar inscribed U. NICOTIAN, 8 in. high—12 guineas.

A small drug pot, painted with birds and foliage in blue, and inscribed CONF. DE. HYACINTH, 3¼ in. high, and a pair of small pots, with cherubs, and inscribed P. TARTARAE and P. FOETIDAE, 3½ in. high—6 guineas.

A drug pot, painted with the arms of the Apothecaries' Company, and Chinese figures in blue, green, and yellow, 9 in. high—10 guineas.

An octagonal pill slab, painted with the arms of the Apothecaries' Company in blue, and motto in black, 10¼ in. by 8½ in.—7 guineas.

Another, nearly similar, with the arms and motto of the Apothecaries' Company in blue, 10¼ in. square—7 guineas.

Another, with the arms of the Apothecaries' Company and the City of London in blue, 10½ in. square—8½ guineas.

Another, painted with the arms of the Apothecaries' Company in blue, yellow, and green, 11 in. by 9¾ in.—8 guineas.

A shield-shaped pill slab, painted with the arms of the Apothecaries' Company in blue, 11 in. by 10¼ in.—7 guineas.

A drug pot, with spout, of Wincanton delft, inscribed RHABARB, 7 in. high, and one, of Liverpool delft, inscribed S. CYDONIAM, 6½ in. high—6 guineas.

## ENCEINTE.

*To the Editor of* THE LANCET.

SIR,—In THE LANCET of Feb. 18th your correspondent "Blancus" says: "There is a striking line in the Bible which says, 'A woman shall compass a man.' ..... The word compass here is surely used in the sense of '*entourer*,' to enclose, or surround. The French is 'La femme environnera l'homme.'" It may interest him to know that there is a French Bible published in 1904, La Haye Imprimerie, C. Blommendaal, C. H. Voorhoeve, successeur, which gives "une femme entourera l'homme."—I am, Sir, yours faithfully,

Feb. 18th 1911. EDW. MAHONY.

## PISTOLS AND THE HOUNDSDITCH MURDERS.

IN summing up to the jury at the inquest upon the body of Sergeant Bentley of the City police, one of the victims of the "Houndsditch murders," Dr. Waldo made observations upon the subject of the indiscriminate carrying of pistols which are in accord with what has been said frequently in the columns of THE LANCET. He seems, however, to have contemplated an unnecessary limit in the restrictions which he suggested should be imposed, if he is rightly reported as having said, "Apart from any illegal act, the possession of deadly weapons by any alien should be forbidden under all circumstances, and any offence against this regulation should be punishable by a fine and imprisonment for a first offence and by permanent deportation for a second offence." The possession of deadly weapons of the type of a magazine pistol should be forbidden to everyone in all circumstances, except to householders and others permitted by licence to keep them in their homes or other premises for the purpose of defending those homes or premises against attack. It should be a punishable offence in anyone to carry a pistol on his person in any place outside the limits of his "curtilage"—of course, with proper exceptions. No one suggests, for example, that a person buying a pistol for the defence of his house, and for his own protection in it, and publicly known to possess a licence for the purpose, should be precluded from acquiring skill in its use by practising at a target in a suitable place. It should be possible in many cases to prevent the introduction of fresh weapons by aliens on their entering the country, but there are plenty of criminal or foolish British subjects who carry pistols and who should be prevented from doing so as far as this is possible. Absolute prevention is, of course, out of the question.

## A DESERVING CASE.

A WELL-KNOWN physician has brought the following circumstances before us. A gentleman formerly engaged in business firms in India had the misfortune to lose his right lower limb above the knee. He is now fitted with an artificial limb, is strong and able to walk about fully, but there is no longer any opportunity for him to take up his work again in India. His training and experience fit him admirably for secretarial work. Our correspondent personally knows the patient and his family, and formerly knew his father, and can testify to the thoroughly meritorious nature of the case. He therefore appeals to readers of THE LANCET for their assistance to obtain for an unfortunate and deserving man some secretarial duties.

---

*M.C.H.*, a medical man, asks for advice concerning the treatment of a case of rapidly growing warts near the frænum. No history of gonorrhœa is given. Some three months ago the first wart appeared and grew rapidly. This was removed and submitted to pathological examination. It was quite soft and waxy and had a broad base. It was a simple papilloma and showed no evidence of malignancy. A month afterwards a similar growth made its appearance about an eighth of an inch higher up the frænum. Its appearance was remarkably rapid—within 24 hours. Now three more have appeared all within a few hours. The rapidity of the growth makes him anxious.

**COMMUNICATIONS not noticed in our present issue will receive attention in our next.**

---

## A DIARY OF CONGRESSES.

WE shall publish this diary from time to time that our readers may have under their hands the dates of the approaching scientific Congresses. It is unnecessary to issue the lists of all these functions week by week, and we propose to make only such gatherings as will occur in the immediate future the subject of regular announcement. The following Congresses, Conferences, and Exhibitions are announced for March, and April, 1911:—

March 2nd–6th (Berlin).—Thirty-second Balneological Congress.
,, 23rd (Paris).—First Congress of French Medical Journalists.
,, 28th–April 25th (Tunis).—Exhibition of Hygiene.
April 4th–7th (London).—Fourth Annual Nursing and Midwifery Conference and Exhibition.

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic (2 P.M.) Hospitals operations are performed daily.

## EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.*

*Lectures, original articles, and reports should be written on one side of the paper only,* AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

*Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.*

*We cannot prescribe or recommend practitioners.*

*Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."*

*Letters relating to the publication, sale and advertising departments of* THE LANCET *should be addressed "To the Manager."*

*We cannot undertake to return MSS. not used.*

## MANAGER'S NOTICES.

### THE INDEX TO THE LANCET.

The Index and Title-page to Vol. II. of 1910 were given in THE LANCET of Dec. 31st, 1910.

### VOLUMES AND CASES.

VOLUMES for the second half of the year 1910 are now ready. Bound in cloth, gilt lettered, price 16*s.*, carriage extra.

Cases for binding the half-year's numbers are now ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

### TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

| FOR THE UNITED KINGDOM. | | TO THE COLONIES AND ABROAD. | |
|---|---|---|---|
| One Year ... ... ... | £1 1 0 | One Year ... ... ... | £1 5 0 |
| Six Months ... ... ... | 0 12 6 | Six Months ... ... ... | 0 14 0 |
| Three Months ... ... | 0 6 6 | Three Months ... ... | 0 7 0 |

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rate of pay, including allowances, is less than Rs. 50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

### TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at these rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

# An Address

ON

# SOME MEDIASTINAL AFFECTIONS.

*Delivered at the Medical Graduates' College and Policlinic on Jan. 30th, 1911,*

BY PERCY KIDD, M.D. OXON., F.R.C.P. LOND.,

PHYSICIAN TO THE LONDON HOSPITAL; CONSULTING PHYSICIAN TO THE HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON, AND TO KING EDWARD VII. SANATORIUM.

GENTLEMEN,—It is not my intention on the present occasion to attempt to deal with the general topic of mediastinal tumours. I wish first to describe briefly certain unusual examples of mediastinal disease, and secondly to discuss some points in the clinical symptoms and diagnosis of tuberculous mediastinal glands.

## I.—UNCOMMON CASES OF MEDIASTINAL DISEASE.

CASE 1. *Substernal thyroid tumour simulating a mediastinal new growth; operation; recovery.*—The patient was admitted into the London Hospital in February, 1906, as a case of mediastinal tumour. For some four years he had suffered from difficulty of breathing. Treatment had given some relief until two weeks before admission, when his breathing became much worse. Two months previously to admission a lump in the neck was first noticed by his medical attendant. The patient was a dark man, of Hebrew race, with an anxious expression, but not obviously wasted. There was slight stridor, mainly inspiratory. The superficial veins of the neck and chest were distended. On coughing a large swelling appeared in the neck above the clavicles, more on the left side, suddenly disappearing when coughing ceased. No lump was felt behind the clavicles. The lungs were hyper-resonant on percussion and the breath sounds were universally weak. There was no dulness over the sternum. The heart was normal. The larynx was healthy; no paralysis of vocal cords, and no dysphagia.

The long history and the absence of wasting seemed to exclude malignant disease, though the evidence of mediastinal pressure was very clear. The diagnosis suggested was substernal thyroid gland. The swelling above the clavicles on coughing was attributed to emphysematous bulging of the apices of the lungs. My colleague, Mr. James Sherren, examined the case, and pointed out that the swelling which appeared in the neck on coughing was dull to percussion, and he suggested that it was due to a moveable substernal thyroid tumour. Radiograms showed a fusiform shadow behind the sternum running up towards the neck. Mr. Hurry Fenwick subsequently saw the patient and agreed to attempt the removal of the tumour.

On March 5th, under chloroform, an incision was made along the upper border of the left clavicle in its outer half. From the inner end of this incision another was carried up and out to the anterior border of the trapezius. The veins were very large and bled freely and had to be ligatured. The platysma and omohyoid (posterior belly) were cut through and a dissection made on to the sheath of the subclavian vessels. No signs of the lump were found. The patient was made to cough and the lump was found to the inner side of the wound. The incision along the line of the clavicle was carried further and more vessels were caught and ligatured, first the muscular head and then the sternal head of the sterno-mastoid muscle had to be cut through. The lump was then found and exposed. A retractor was put on to hold back the soft structures and the swelling was grasped by tenaculum forceps and pulled out. On puncture yellow cystic fluid escaped. The lump, now smaller, was pulled on and eventually shelled out of its bed. It was much larger than at first suspected and was about the size of a large William pear. There were no adhesions. The tumour was continuous with the isthmus of the thyroid gland. The junction was cut through, the vessels ligatured, and the surface cauterised. The cavity occupied by the tumour reached down into the thorax behind the arch of the aorta. A drainage-tube was inserted in the cavity. The tumour proved to be an encapsulated adenoma. The wound healed fairly well, but some suppuration took place.

The patient was discharged on March 30th. When I saw him a few weeks later the wound had healed and no abnormal physical signs could be detected. The patient was completely relieved of all his symptoms. I have given the full surgical notes of Mr. Hurry Fenwick's operation as the case is an unusual and instructive one, and the results were highly satisfactory.

CASE 2. *Mediastinal cyst (? dermoid).*—The patient, who was 20 years of age, had suffered from a dry cough from January to Easter, 1891, when he was suddenly seized with sharp pain in the left side and shortness of breath. Signs of pleural effusion developed and he was tapped, a quart of clear yellow fluid being withdrawn. A week later he was aspirated again, the result being a tumblerful of turbid fluid with flakes floating in it. Since then he had dragging pain on raising the left arm, and dyspnœa. In August, 1891, a swelling appeared in the upper part of the subcostal angle. I saw the patient at the Brompton Hospital as an out-patient in October, and he was admitted under my care through the kindness of my colleague, Dr. F. T. Roberts. Physical examination showed dulness and signs of fluid on the left side from the second space in front and the spine of the scapula behind to the base. The heart was displaced to the right of the sternum. On the right side in front from the clavicle to the third space there was a vertical strip of dulness extending from the middle line of the sternum outwards to the right for 1½ inches. Immediately below the ensiform cartilage there was a rounded, slightly pulsating elastic swelling. The signs were somewhat puzzling. For although the evidence of fluid in the left pleura was unmistakeable, the patch of dulness to the right of the upper part of the sternum and the epigastric tumour were difficult to explain. The possibility of an encysted mediastinal empyema was suggested.

On Oct. 15th the patient was aspirated by Mr. R. J. Godlee in the eighth space in the scapular line, and 65 ounces of dark blood-stained fluid were drawn off. Microscopically red blood corpuscles, leucocytes, and spherical epithelial cells with large nuclei and granular débris were found. The dulness on the left side diminished, but the epigastric swelling and the patch of dulness to the right of the sternum persisted. I will now quote Mr. Godlee's account of the subsequent history of the case.[1]

> On Nov. 28th an incision was made into the epigastric swelling which was becoming more tense, and a cavity was opened containing a considerable quantity (6 or 7 ounces) of brown purulent fluid something like that previously extracted from the side, floating in which were numerous small rounded masses of a brilliant chrome-yellow pultaceous material, looking like the yellow palm oil used for lubricating the wheels of railway carriages. The cavity extended upwards behind the sternum, and on a subsequent occasion I endeavoured to discover its upper limit by making a hole through the sternum. The finger, however, was found to be amongst the large vessels in the superior mediastinum and I did not venture to go any further. An elaborate analysis of this fatty material was made by Dr. Halliburton, but it threw no light on the case. We never found any of the usual contents of dermoid cysts and I do not therefore know whether the case should be placed here [i.e., chapter Dermoid Cysts]; but I am at a loss for any other explanation of it. The yellow material continued to escape for a considerable time and ultimately the sinus closed. It remained healed for some time, but subsequently a small ulcer formed at the top of the sternum, which, after discharging for some months, finally healed

I saw the patient myself in 1897—i.e., about five years after the operation—when he was in excellent health. There was a small scar just above the right sterno-clavicular joint, and deep scars over the lower end of the sternum and epigastrium in the site of the two operations. With the exception of slight deficiency of movement on the left side of the chest there were no abnormal physical signs.

CASE 3. *Mediastinal abscess perforating the trachea and œsophagus and causing subcutaneous emphysema and cellulitis.*—The patient, a man aged 37 years, was admitted into the London Hospital on Oct. 4th, 1900. He had been taken ill seven days previously with a shivering fit and sweating, and shortly afterwards he had noticed a red swelling in the neck. The swelling had been much worse a few days previously to admission, diminishing suddenly after spitting up much phlegm. On admission the patient was cyanosed, and the skin of the lower part of the neck was congested and boggy, and emphysematous crackling was detected. The pulse was 138, the respirations were 42, and the temperature was 100·8° F. There was dulness to percussion over the lower

[1] Fowler and Godlee: Diseases of the Lungs, p. 698.

two-thirds of the left lung, and tubular breathing at the base. On the right side scattered rhonchi. Diagnosis: Cellulitis of neck; pneumonia. The patient was bled 10 ounces, and an incision was made in his neck, when some pus and a few bubbles of air escaped. Temporary relief was obtained, but he sank and died on Oct. 6th, two days after admission.

At the necropsy the left pleura was found to contain 1½ pints of brownish turbid fluid, the lung being collapsed and covered with recent greenish lymph. Both lungs contained numerous miliary abscesses. In the œsophagus opposite the bifurcation of the trachea there was a flat oval fibroma measuring 1×⅔ inch, and just to the left of the tumour a small smooth-edged opening led into an abscess cavity at the bifurcation of the trachea. This abscess had extended upwards into the neck and into the left pleura and communicated by a small opening with the trachea. There was also acute recent pericarditis. The disease appeared to have originated in the sub-tracheal lymphatic glands, whether as the result of tuberculosis or some other cause could not be determined. No tuberculous focus was discovered anywhere.

The following two cases, which I will only briefly outline, illustrate the way in which mediastinal growths may be masked by other conditions.

CASE 4. *Mediastinal growth masked by pericardial effusion.*—A labourer, aged 61 years, had been ailing for four weeks with loss of appetite followed by dyspnœa and weakness. There were physical signs of pericardial effusion. He died 15 days after admission.

At the post-mortem examination the mediastinal glands in front of the trachea and bronchi were found to be infiltrated with a firm whitish-yellow growth forming a mass of about the size of a duck's egg, not occluding or narrowing either bronchus, trachea, or œsophagus. There was a small nodule of growth in the upper lobe of the left lung. The pericardium was roughened with lymph and contained 1½ pints of clear fluid but no growth.

CASE 5. *Mediastinal growth masked by pleural effusion.*—A man, aged 50 years, had been ailing for five months with loss of flesh, pain in the right side, and swelling of the legs. There were physical signs of a small pleural effusion on the right side which steadily increased, and the patient died four days after admission.

Post mortem a large pleural effusion was found on the right side and turbid fluid with flakes of lymph. The trachea and the root of each lung were embedded in a large whitish growth extending widely into the lower lobe of the right lung. The œsophagus and large veins were not involved.

## II.—TUBERCULOUS DISEASE OF THE BRONCHIAL GLANDS.

It is well known that the mediastinal glands may be markedly caseous and considerably enlarged without exciting any suspicion of the actual state of things. This mistake is less likely to occur in children than adults owing to the greater tendency in the former to the development of bronchial obstruction depending on the more yielding character of their bronchial walls. Nevertheless, in children also extensive tuberculous disease of the bronchial glands is very apt to pass unrecognised, even though careful search for its presence be instituted.

The mediastinal glands may be divided into two main groups—anterior and posterior. The former lie in front of the trachea, the posterior group is situated beneath the fork of the trachea and around the main bronchi. The latter group is more often affected by tuberculosis. When the glandular swelling is considerable symptoms of mediastinal tumour may be presented with characteristic pressure signs. If the pre-tracheal glands be chiefly involved the superficial thoracic veins may be enlarged and dulness on percussion may be elicited over the manubrium sterni. More often, perhaps, the pressure is not confined to the trachea, but is exerted also on one or other bronchus, giving rise to weakening of the vesicular murmur over the corresponding lung. In some cases slight stridor is met with. It may be said that enlargement of the pre-tracheal glands gives more definite physical signs and is easier to recognise.

In the case of the posterior or sub-tracheal glands very considerable enlargement may exist without betraying its presence by any obtrusive signs. It is commonly asserted that dulness to percussion may be detected in these circumstances in the interscapular region. But from the position of the glands lying beneath the bifurcation of the trachea and in front of the body of the third dorsal vertebra, this seems very unlikely unless the vertebral border of the lung be involved also, or unless the glands around the main bronchi be enormously enlarged. According to my experience, dulness in this situation is never found in tuberculous adenitis when the lung is unaffected. Among the occasional symptoms mention must be made of a paroxysmal cough and alterations in the frequency of the pulse, whether slowing or acceleration, attributed to pressure on the vagus. Paralysis of the vocal cords is said to occur, but I have never met with it, or perhaps I should say I have never been able to establish its dependence on tuberculous bronchial glands. But not much reliance can be placed on these symptoms for purposes of diagnosis. The same may be said of Dr. Eustace Smith's sign, a continuous humming murmur heard over the manubrium when the head is strongly retracted. I will now give a few examples illustrative of these points.

CASE 6. *Tuberculosis of mediastinal glands followed by pleurisy with effusion; recovery for some years; death from tuberculous meningitis.*—A boy, aged 5 years, had suffered from tuberculous disease of the knee-joint from the age of 3 years. Amputation had to be performed a year later, from which he recovered well and his general health improved greatly. But soon afterwards he began to wheeze and his breathing was noisy at times. On examining him I found slight stridor, the percussion note was slightly impaired at the apex of the right lung, especially front, and the breath sounds were much weaker on this side. No adventitious sounds could be heard. Diagnosis: Tuberculosis of mediastinal glands compressing right bronchus. Some months later a large pleural effusion developed on the right side, from which he made an excellent recovery, the fluid becoming absorbed in less than a month. The signs at the right apex gradually cleared up in the course of two or three years, leaving nothing beyond deficient expansion and broncho-vesicular breathing. After regaining fairly good health for some years he died at the age of 18 from tuberculous meningitis. No necropsy was made.

CASE 7. *Tuberculosis of mediastinal glands compressing the right bronchus; recovery.*—A girl, aged 8 years, a cousin of the last patient, a few months after an attack of whooping-cough began to suffer from a peculiar wheezing and occasional cough. About the same time she had an obscure febrile attack resembling rheumatism. The following winter she had bronchitis. When I saw her she was pale and her face was rather puffy, but she was plump and well nourished. The superficial veins over the upper thorax were enlarged. Percussion at the right supraspinous fossa was slightly impaired, the breath sounds at the right apex were diminished, and sibilant rhonchi were heard at both apices. Diagnosis: Tuberculosis of bronchial glands compressing right bronchus. She was sent to Brighton for the winter and made an excellent recovery. All abnormal signs gradually disappeared and she grew up into a healthy woman, and is now 27 years of age.

In these two cases (Cases 6 and 7) the signs of obstruction of the right bronchus without any symptoms or signs of pulmonary disease pointed strongly to the bronchial glands as the source of the trouble.

CASE 8. *Tuberculosis of mediastinal glands involving the lung by direct infection through the bronchi.*—The patient, a boy aged 7 years, was admitted to hospital on Nov. 1st, 1905. Three weeks previously he had come home from school complaining of pain in the head and of feeling "burning hot." Vomiting and diarrhœa developed and he became languid and miserable. Five months previously he had had scarlet fever, since when he had never been well. On admission the boy was found to be pale and wasted and the temperature was irregularly remittent—103°-99° F. There was occasional cough. Physical examination showed a patch of dulness over the upper third of the sternum merging into another limited area of dulness, just to the right of the sternum, about 2 inches in width, between the fourth and sixth ribs. Over the dull areas prolonged expiration was heard, but no adventitious sounds anywhere. Diagnosis: Tuberculosis of anterior mediastinal glands involving the middle lobe of the right lung. The opsonic index to tuberculosis was estimated on four occasions by Dr. G. T. Western in November and varied from 1·0 to 1·19. The case progressed slowly downwards, the chief features being remittent pyrexia, loss of flesh, and slight cough.

Signs of consolidation gradually spread up towards the apex of the right lung, râles and rhonchi appeared over both lungs, and the patient died from tuberculous meningitis on June 10th, 1906.

At the necropsy large caseous glands were found in the anterior mediastinum and beneath the fork of the trachea. The right bronchus was perforated by the caseous glands in two of its divisions—the branch to the middle and the branch to the lower lobe. The middle lobe of the right lung was converted into a large caseous mass. In the upper lobe there were a limited fibrosis and a small cavity. Both lungs were studded with miliary tubercles. There was tuberculous meningitis.

Perforation of the bronchi by caseous bronchial glands is not an uncommon event, and explains the anomalous distribution of the pulmonary lesions in this and similar cases.

It would be easy to cite from post-mortem records examples of tuberculous bronchial glands undetected during life. I will merely give as an illustration one case that proved extremely deceptive.

CASE 9. *Tuberculous abscess of bronchial glands; broncho-pneumonia simulating acute tuberculosis; death from septicæmia.*—A boy, aged 7 years, had been ailing for 17 days with headache, malaise, cough, and wasting. One other child had died at home three weeks ago with similar symptoms. On admission the boy was only partly conscious, groaning frequently, and coughing occasionally. The respirations were 44 and the temperature was 101°-103° F. At the base of the left lung there were dulness and tubular breathing, and crepitations were scattered over both lungs. Diagnosis: acute tuberculosis. The patient died in a few days.

At the necropsy enlarged caseous glands were found in the posterior mediastinum, and in the fork of the trachea was an abscess with foul stinking pus tracking along the right bronchus, but not communicating with the air passages or œsophagus. The left pleura contained one pint of serous fluid, the lung being collapsed. In the right lung were patches of broncho-pneumonia, but no tubercles. There were a few small caseous nodules in the liver and the kidneys.

Cases like the preceding testify to the inadequacy of our standard methods of diagnosis. For while we can recognise with a fair degree of accuracy gross lesions of the mediastinal glands, moderate enlargements of these glands frequently escape us altogether. At the last annual meeting of the British Medical Association Professor d'Espine of Geneva read a paper on The Early Diagnosis of Tuberculous Bronchial Adenopathy in the Child. In this paper he claimed that the presence of enlarged bronchial glands could be determined by auscultation over the spinous processes of the seventh cervical and upper two or three dorsal vertebræ. Pectoriloquy, or a bronchial quality of respiration, in this situation was held to be a certain sign of enlarged sub-tracheal glands. Pectoriloquy is stated to be an earlier sign than bronchial breathing. A definite vertebral dulness on percussion over the same area coincides invariably with a loud bronchophony, and is pathognomonic of a large glandular mass uniting the trachea with the vertebræ.

If these statements can be verified obviously we should have received a most valuable addition to our means of diagnosis. It was surprising to find from the report of the meeting[2] that these statements were allowed to pass without further discussion.

In his work on "Auscultation and Percussion" (second edition, p. 126) Dr. S. J. Gee writes as follows: "Bronchial breathing, like bronchophony, is heard about the seventh cervical, and three or four upper dorsal vertebræ in a great number of healthy persons, especially in those that are thin, in women, and children." Dr. Gee cites Laennec in support of this statement. I remember Dr. Gee making use of this fact in teaching auscultation, and pointing out how auscultation of the spine in this region provides us with a standard of what is bronchial breathing, which is very useful to students and beginners when in doubt as to the character of the breath sounds heard over the lungs. I thought this fact was generally admitted. I have repeatedly verified it myself and I have often adopted Dr. Gee's plan in teaching students. But after reading Professor d'Espine's remarks I determined to investigate the point anew. Accordingly, with the help of my house physician, Mr. J. R. Dick, I examined 51 patients consecutively with reference to this matter. The only patients excluded were such as had consolidation of the lung of any kind, pleural effusion, or any evidence of tuberculous or other glandular disease in any district of the body. Of these 51 patients, 33 showed bronchial breathing or pectoriloquy over the seventh cervical and upper dorsal spines, usually the first and second. In 22 cases both bronchial breathing and pectoriloquy were present; in 11 cases either bronchial breathing or pectoriloquy alone. In 18 cases the results were uncertain or negative. Most of the patients that gave positive results were spare or thin, but not all, a notable exception being a man weighing over 15 stones, the subject of a cerebral tumour. Among the positive cases 19 were male and 14 female. Age: under 10 years, 7 cases; 10 years and over, 26 cases. In one infant 11 weeks of age suffering from disseminated broncho-pneumonia we found marked bronchial breathing over the seventh cervical and first dorsal spine but nowhere else. The necropsy showed scattered foci of broncho-pneumonia and trifling enlargement of the bronchial glands; in fact, the glands were scarcely larger than usual in healthy infants. These facts appear to recommend an attitude of caution with respect to Professor d'Espine's views. I feel persuaded myself that Dr. Gee's statement is true and that we may expect to find bronchial breathing and pectoriloquy over the upper dorsal spines in many healthy people.

In some cases radiography gives valuable assistance, but it is not possible to secure expert examination in all cases. In infants under 2 or 3 years of age von Pirquet's cutaneous tuberculin test is a very useful addition to other means of diagnosis. But in older children and adults it has a more limited value owing to the great frequency of quiescent or arrested tuberculous lesions in the lungs and other parts after the second or third years of life.

I cannot now enter into the question of treatment further than to urge the very great importance of recognising the curability of tuberculous lymphatic glands in the chest as in other parts, and, in the case of children especially, of insisting on prolonged residence at the seaside.

MEDICAL SICKNESS AND ACCIDENT SOCIETY.—The usual monthly meeting of the executive committee of the Medical Sickness, Annuity, and Life Assurance Society was held at 429, Strand, London, W.C., on Feb. 17th, 1911. There were present: Dr. F. de Havilland Hall (in the chair), Dr. H. A. Sansom, Dr. Frederick S. Palmer, Dr. M. G. Biggs, Dr. W. Knowsley Sibley, Mr. Frederick Wallace, Dr. F. C. Martley, Dr. M. Greenwood, Dr. J. W. Hunt, Mr. E. Bartlett, Dr. J. Brindley-James, Mr. H. P. Symonds, Mr. J. F. Colyer, Dr. F. J. Allan, Mr. F. S. Edwards, and Dr. J. B. Ball. A large increase has taken place in the number of new entrants, and the amount disbursed in sickness pay has been under the average and remarkably small for the season of the year. Prospectuses and all further particulars on application to Mr. F. Addiscott, secretary, Medical Sickness and Accident Society, 33, Chancery-lane, London, W.C.

THE WEST HERTS HOSPITAL AND THE MEDICAL TREATMENT OF SCHOOL CHILDREN.—At a meeting of the Hemel Hempstead Education Committee held recently the clerk reported that he had, by direction of the committee, interviewed the committee of the West Herts Hospital as to the treatment of school children found on medical inspection to require treatment, and discussed the matter with them. The great difficulty, so far as the hospital was concerned, was that although it might be prepared to treat suitable cases referred to it, and to accept payment for the same from the school authority, still it would be unfair to the honorary medical staff, in that the hospital would benefit to the amount of the subscription from the school authority, and the medical staff would be called upon to exercise the charity by attending these children, for treating whom they would get nothing. The education committee had set very expensive machinery in motion to discover the defects of these children, and they were strongly of opinion that some scheme of payment should emanate from the Board of Education. A member of the education committee said that it was a waste of time to discover the defects in school children unless those defects when discovered were remedied, adding that the Board of Education had distinctly promised a grant in aid. The clerk was instructed to write to the Board on the matter.

ON

# THE IMMUNITY REACTION IN DIAGNOSIS, ESPECIALLY OF TUBERCULOSIS AND SYPHILIS.

*Delivered in the Theatre of the Royal College of Surgeons of England on Feb. 6th and 8th, 1911,*

BY W. D'ESTE EMERY, M.D., B.Sc. LOND., M.R.C.S. ENG.,

PATHOLOGIST AND LECTURER ON PATHOLOGY AND BACTERIOLOGY AT KING'S COLLEGE HOSPITAL.

## LECTURE II.[1]

*Delivered on Feb. 8th.*

## THE APPLICATION AND INTERPRETATION OF THE WASSERMANN REACTION, WITH A DESCRIPTION OF A SIMPLE AND ACCURATE QUANTITATIVE METHOD.

MR. PRESIDENT AND GENTLEMEN,—The importance of an accurate method for the diagnosis of syphilis cannot be over-estimated. Even where there are active and visible lesions the most experienced clinical observer is often in doubt, and when the lesion is inaccessible—such as an intracranial gumma—the recognition of its nature is usually impossible, and much valuable time is often wasted in trying the effect of antisyphilitic treatment. The question is even more important from a sociological point of view, in regard to the question of marriage after syphilis. I believe most strongly that the Wassermann reaction, properly applied and properly interpreted, answers every requirement that the clinician can reasonably demand of the pathologist. Let me outline the steps by which it was discovered, so as to be able to give a more intelligible description of the principles on which it depends.

### ORIGIN OF THE WASSERMANN REACTION.

Bordet and Gengou discovered the phenomenon of the absorption of complement in presence of a mixture of a bacterial culture or extract and its appropriate antibody. It did not, however, attract general attention for several years, when it was put to practical use by several German observers, amongst others by Wassermann By this time the Treponema pallidum, the true cause of syphilis, had been discovered by Schaudinn, and it was only natural to attempt to make use of the Bordet-Gengou reaction in the diagnosis of the disease. Here there was a great difficulty: the organism could not be cultivated, so that neither an emulsion nor an extract could be obtained. The discovery of the fact that spirochætes swarm in vast numbers in the livers of macerated syphilitic fœtuses suggested to Wassermann the idea of making use of an extract of such an organ in normal saline solution as the reacting substance in the test. It answered admirably; when mixed with syphilitic serum it absorbed complement greedily, whereas when mixed with normal serum it had no such action. At first this test involved the use of a syphilitic liver very rich in parasites. This is not always easily obtained, and the material was difficult to preserve. But in a very short time Levaditi and several other observers found that an alcoholic extract would answer as well, or nearly as well, as an extract in normal saline solution, and further that it was unnecessary to use syphilitic material at all; an alcoholic extract of normal liver or heart of man or of the lower animals would give the reaction in just the same way. This had the effect of making the tests much more easy and accessible to pathologists, but it had also the effect of showing us that our theories as to its causation were entirely erroneous. Further research seemed to show that the substance or substances which occur in the extract and act as an antigen are of a fatty nature, and many but not all fats will act in this way. The extract can, indeed, be replaced by comparatively simple chemical substances, such as lecithin; and although these artificial extracts have not proved so useful in practice as solutions of tissues, they serve to show beyond doubt that the substances involved are not proteid in nature and therefore not true antigens.

### NATURE OF THE REACTION.

This raises new and very important questions as to the nature of the second substance involved—the substance which occurs in the serum and which acts as an antibody. It is certain that it is not a true antibody, and yet it appears to act in exactly the same way in the absorption of complement. Further, it is not strictly specific, for further observations showed that it occurred in other diseases. In the great majority of diseases it does not occur, or occurs only in amounts such as are met with in health. For, and this is a point on which I wish to lay stress, it is always present in normal serum, and the only change which occurs in syphilis is its appearance in greatly increased amount. All sera will give some absorption of complement with this extract of heart or liver if the latter be sufficiently strong. This is usually expressed by saying that the extract absorbs some complement, but I see no reason whatever for distinguishing between this absorption with normal sera and the vastly more powerful absorption which takes place with most syphilitic sera. All grades occur. If a person with a chancre be examined early in the disease his serum will absorb complement (in contact with extract) just like that of a normal person. As the case is watched the absorption grows gradually stronger, so that it appears with extract which has been diluted to such an extent that it is devoid of action on normal serum. Where is it possible to draw the line, and to say that this is a non-specific absorption of complement due to the extract alone, and this is a specific absorption due to the presence of a substance characteristic of syphilis? It seems reasonable to suppose that the reaction in syphilis is due simply to an increase in amount of a substance which is present in health. It is possible that the substance is a lipoid compound, and it may perhaps represent a product of metabolism of the tissues. In health we must suppose that it is given off in very small amount, whereas in those diseases which give the Wassermann reaction the amount is greatly increased. This we may probably attribute in some way to the breaking down of the tissues which forms so important a feature in the disease. In very general terms the amount of the substance, as judged by the strength of the reaction given by the serum, is proportionate to the severity of the case, and to the extent of the active lesions. This I believe to be true with one important exception; very powerful reactions are often (though not invariably) met with in hereditary syphilis, even when there is no evidence of any active pathological process. This is very difficult to explain. Perhaps in a person with hereditary syphilis the tissues, or some of them, have become trained to an alteration in their metabolism, so that there is a greater output of the reacting substance, though without any obvious degenerative changes. If this is so it might account for the greater difficulty in abolishing the reaction in hereditary than in acquired cases; it is easy to believe that such an ingrained alteration of metabolism, acquired in early life and continued for years, might lead to a permanent physiological alteration in the tissues. Be this as it may, a high degree of strength in the Wassermann reaction in hereditary cases means less than the same degree in acquired disease, and is less easily removed by mercurial treatment.

### MECHANISM.

Next, as to the mechanism of the reaction. How are we to account for the absorption of complement if it is not due, as in other cases of the Bordet-Gengou reaction, to an interaction of antigen and antibody? Absorption of complement takes place under several different classes of conditions, amongst others under all circumstances in which a solid precipitate is formed; for example, when complement is carried down quasi-mechanically by a precipitate of barium sulphate, as in Wechselmann's method. Now there is proof that the reacting substance in the syphilitic blood does, as a matter of fact, combine with, and precipitate, the fatty substances in the so-called antigen. This is the basis of Porges' test for syphilis; clear serum is added to a solution of lecithin or other lipoid substances, and in many cases will be found to give a precipitate. This has been tried extensively as a simple method to replace the Wassermann

[1] Lecture I. was published in THE LANCET of Feb. 25th, 1911, p. 435.

reaction, but it appears not to be so delicate. This is only what we might expect from other facts known in connexion with complement absorption; this phenomenon is a very delicate test for the formation of an insoluble precipitate, giving indication of its presence when no precipitate whatever is visible to the naked eye. Thus in the test for the nature of blood by means of the precipitin reaction the test is infinitely more delicate if the question of the presence or absence is determined by complement absorption rather than by the presence or absence of a precipitate; it is said that by the former method so little as one-millionth part of a cubic centimetre of blood can be recognised.

It is not absolutely certain that the Wassermann reaction is due to the same precipitation which causes Porges' reaction, but the proof that the absorption of complement in the former cases is due to a process akin to precipitation has been given by Jacobsthal, who studied the behaviour of mixtures of serum and antigen under the ultra-microscope. He found that when a normal serum was used the minute particles of lipoid substance in the antigen appeared as brilliant points, isolated from one another and having active Brownian movement. But when a syphilitic serum was used these points of light ran together to form a large and brilliant mass; with a weakly reacting serum a sort of partial precipitation occurred, the bright points grouping themselves into small masses or chains. These phenomena were found to run parallel to the Wassermann reaction, which they might perhaps replace.

It would appear, therefore, that we can explain the Wassermann reaction somewhat as follows. The dilution of the alcoholic solution of fatty substances with normal saline solution gives rise to the production of an emulsion of extremely minute particles of fat, which form a more or less permanent suspension in the fluid. The syphilitic serum contains a substance which has the power of combining with these fatty particles, and in so doing of altering in some way the surface-tension between them and the fluid in which they are suspended, so that they clump, and in doing so attract to themselves any complement which may be present in the fluid. The process is partly chemical and partly physical, if there is in truth a difference between the two, and in this connexion it is important to notice some facts about the alcoholic solution of so-called antigen which are of great importance in actual practice. The first is its variability. This constitutes the chief difficulty in the use of the reaction and is probably one of the chief causes of erroneous results. An alcoholic extract filtered from sediment is far indeed from remaining of constant strength. As a rule, it tends to become stronger, so that if the phenomenon is not recognised and an appropriate dilution used every blood may give a positive reaction. I have had an extract which got four times as strong as formerly in the space of two days. Occasionally the reverse occurs, and an extract may become quite inert; the change may be sudden or gradual. I think, as a rule, it is unwise to continue to use extracts which have undergone any noticeable change in strength, even if it is allowed for in the dilution. I imagine the change indicates an alteration in the molecular composition of the fatty substances in the extract, so that the size and number of the particles which they form when diluted with a watery fluid are altered.

The other interesting point is the fact (which I believe was first pointed out by Bayly) that the diluted extract is more turbid and has a more powerful action if the two fluids are allowed to diffuse gradually the one into the other and not mixed at once. This has an obvious practical bearing: the one or other process must be employed throughout. I float my alcoholic solution on the top of the normal saline and allow them to diffuse together gradually for ten minutes or so and then slowly stir them together.

### TRUSTWORTHINESS OF THE REACTION.

When a new test is introduced the pathologist is constantly asked questions as to its trustworthiness, and the clinician very naturally wishes for a test that shall give 100 per cent. of positive results when the disease is present and none at all in its absence. Now with regard to the latter point, I do not think that there is any reason whatever to think that any of the diseases which are indigenous in this country (with the possible exception of scarlet fever, which may cause it for a short period) ever give rise to the reaction or that it ever occurs in health. But it is universally admitted that a certain small percentage of cases of undoubted syphilis do not react, and this has been used to discredit the reaction altogether, though most unjustly. Now it is extremely difficult to see any theoretical reason for the occasional failure of a reaction which occurs in the vast majority of cases of the disease, and I should like to ask whether it is not possible that these apparent exceptions occur from the use of methods which may cause a weak reaction to be missed or from the use of reagents which have altered in constitution. I wish to state most emphatically that I believe very good results can be obtained from all, or very nearly all, of the processes which have been employed—results so good that they constitute a priceless boon to the diagnostician. My reason for a comparatively long discussion into the technique of the different methods is to point out that with several of them there are combinations of conditions which may lead to an erroneous result, and that some, at least, of these may be avoided by the use of very simple and rapid methods.

Here I must point out that the advantage to be claimed for a simple method is not that it facilitates the work of the pathologist. The benefits that accrue from such a method, if equally accurate, are four in number: more tests can be made in a given time, so that there need be no hesitation in having the blood tested in every case, even where the diagnosis is improbable; the test can be completed and the result obtained quickly enough for ordinary out-patient work, so that the surgeon may know the result of the examination before prescribing for the patient; the possibility for technical error is greatly reduced; and lastly, and most important, quantitative work can be carried out by a process of trial, the result of one test being obtained before the next is commenced. I will explain what I mean by this shortly.

### TECHNIQUE OF THE VARIOUS METHODS.

Let me examine in brief the principles of the chief variants in the method that have been proposed. The original process, the so-called "classical" Wassermann reaction, which is used, with some slight modifications, by most of the workers in this branch, commences by removing the complement originally present in the serum. Leaving aside for a moment the alleged reason for this, let us turn to the methods in which it can be done. These are threefold. Firstly, we may heat the serum to 55° or 60° C.; this is the method that is usually employed, and it has the advantage of being quick and easy. Unfortunately, however, it appears that the temperature employed may weaken or hide the reaction, possibly by linking together the complement and some of the so-called syphilitic antibody, so that some of this substance is rendered inert and unable to combine with the antigen. The effect of this, if sufficiently marked, is to cause a negative reaction where methods which do not require heat would give a positive one. The second method—that of Wechselmann—involves the absorption of the complement with an inert substance, barium sulphate; it is theoretically sound, but somewhat complicated, and I do not think it is used practically to any considerable extent. Lastly, McDonagh has tried keeping the sera until the complement disappears spontaneously. This takes some days, which renders it entirely unsuitable for clinical work.

Having got rid of the natural complement the investigator next proceeds to add some fresh, in the form of guinea-pig serum. The question naturally arises, Why take the trouble to get rid of the complement when the next step is to replace it? It is not that which is present is unsuitable in quality; on the contrary, it will act perfectly well. The explanation given is that the natural complement present in human serum varies so greatly in amount that it makes the test unreliable. I have seen no proof of this, and from my own experience deny it most absolutely. I admit fully that if the amount of complement be tested on insufficiently sensitised corpuscles the amount of the former may be deficient, and this was my chief reason for abandoning the use of Fleming's method. Leaving this question for the present, let us turn to the way in which uniformity in the amount of complement is secured. This is accomplished as a rule by the addition of a known amount of guinea-pig's serum, no attempt being made to examine this to see what quantity of complement it actually contains, and yet the amount is well known to vary in different animals. Further, many workers keep the serum in the ice-chest for two or three days, or even more, regardless of the fact that the complement undergoes a rapid fall in amount and a remarkable qualitative change as well.

Others dry it on filter paper and make a solution for the purposes of the test; the amount obtained in this way must vary enormously. Thus it seems very doubtful whether these elaborate processes do as a rule secure the uniformity of complement which is supposed, erroneously, I believe, to be so essential.

Some observers do, it is true, attempt an evaluation of the complement in the serum and proceed accordingly. This is more scientific, but it is also very tedious, and I think not usually done. There is this objection even to this; the process takes some time (as usually carried out; it can be done more quickly by other methods), and during the time taken in testing it the amount in the part remaining is altering. In some cases this is not a serious objection, but it is a decided drawback where consecutive quantitative estimations have to be made, for with so delicate a substance it is not safe to assume that a value obtained on one day is true on the next.

### USE OF UNHEATED SERUM.

Let us consider in detail the objection to the use of unheated serum. The only errors which could arise would be due to the amount of complement being too small or too great. Too small an amount of complement would result in the production of a negative result where there should be a positive one: the extract absorbs some complement from a normal serum, and if the total amount were but small might be sufficient just to turn the scale, so that whereas the control tube without extract would show hæmolysis, the tube with extract would show none. This seems plausible, but, as a matter of fact, it is got over with the greatest ease; it all turns on the strength of the antigen, and if this is standardised in such a way that normal sera do *not* give the reaction (as I shall describe subsequently) the objection falls to the ground. But in this connexion much stress must be laid on the fact that the corpuscles must be fully sensitised, for if they are not they may show no sign of hæmolysis in presence of a trace of complement, though capable of full solution if sufficient of that substance is present. Again, as a matter of fact, an experience with over 500 sera has shown me that, provided the serum is not more than 24 or 36 hours old, and provided also that the sensitised corpuscles are added in the proportions I recommend (which has been worked out so as to be suitable for the average amount of complement in fresh human serum), such a phenomenon as I have described does not occur. I have only met with a single specimen (from a severe case of myelogenous leucocythæmia) which did not give enough complement for the reaction.

On the other hand, it may be objected that the amount of complement may be so large that it cannot all be absorbed by the antibody-antigen combination. This is a more valid objection, and I can only answer that I have never found any reason to believe that it ever occurs. I have often obtained weak positive reactions with sera having a very powerful hæmolytic action, but the conditions for a crucial test—an altogether exceptionally large amount of complement in a patient in whom we should expect, but do not find, a very faint positive reaction—have not occurred in my experience so far. I know from experience that a *strong* reaction is not masked in this way, whatever the amount of complement. But Noguchi, who leaves the original complement present and adds fresh, apparently gets very good results. Apparently, therefore, the presence of much more complement than ever occurs in natural human sera does not vitiate the result.

The idea that any error actually arises from variations in the amount of complement—avoidable errors, perhaps I should say—I believe to be entirely erroneous. As I remarked in my previous lecture, the hæmolytic system is simply an indicator, and is used only to see whether a certain combination has taken place, and provided there is neither excess nor deficiency, there is no more reason for getting exactly the same amount every time than there is for adding the same amount of litmus to a fluid we are titrating; and my chief endeavour in presuming to add another to the already long list of modifications of the reaction, is that I believe I have arranged the quantities of the other ingredients in the test so that they will react properly with any degree of complement within the normal limits.

### EMPLOYMENT OF SHEEP'S CORPUSCLES.

The processes which do not involve the removal and subsequent addition of complement may be classified under two heads. In the first, advantage is taken of the fact that human serum will, as a rule, hæmolyse sheep's corpuscles without the addition of an artificial immune serum; it contains an amboceptor which will link up its complement to these corpuscles. This is the basis of Hecht's method, which under Fleming's modification is largely used in this country. It is quite a good method, but it has some drawbacks. In the first place, the amboceptor is not always present, or, if present, not to an extent sufficient to cause hæmolysis with the complement also present, and in this case the test is useless unless serum from a known non-syphilitic person is added also. This, of course, is easy, but it is by no means so easy to say what amount should be added, for the addition involves *two* unknown substances (complement and amboceptor), one of which (the amboceptor) is by no means easy to estimate quantitatively. It is surely better always to add amboceptor in known amount, so as to get amply sufficient to sensitise the corpuscles to small traces of complement. The number of cases in which the test fails in its simpler form is variously stated at from 10 to 30 per cent. My own experience with it approached the latter figure, and I found that sera which gave no trace of hæmolysis with sheep's corpuscles reacted perfectly with fully sensitised human corpuscles; in one batch of seven sera four failed to react by Fleming's method, whereas all reacted next day by my own although, of course, the complement was weaker. It was from observations like these that I was led to the belief that the failures of the sheep's corpuscle methods are due to deficient amboceptor and not to insufficient complement.

Another objection I have to the method is that it is unnecessarily slow. The actual manipulation is quick and easy (the technique of Fleming's modification, apart from the differences in the reagents, is almost identical with my own), but the process is longer with the sheep's corpuscles because the human serum, although it contains amboceptor, contains no agglutinin, so that sedimentation is much slower. Using sensitised and agglutinated corpuscles, I can, if need be, perform the test in ten minutes. This is of enormous advantage in quantitative work, as well as in out-patient practice.

### EMPLOYMENT OF HUMAN CORPUSCLES.

In the next group of methods human corpuscles are used, and this, of course, involves the use of an immune serum to supply the necessary amboceptor to link up the pre-existing complement. This includes Tschernugobow's process, Noguchi's, Birt's, and my own. These methods have the great practical advantage that human corpuscles are always obtainable.

Noguchi's test thus seems to be more sound theoretically than Wassermann's, and observers who have performed parallel tests with the two speak highly of its value. But it is open to this objection: Noguchi, though he does not decomplement his serum, adds guinea-pig serum. Now this is unnecessary, and adds a useless reagent, besides which it is wrong, for the only error which could arise is that due to a possible excess of the natural complement, and not to its deficiency. Tschernugobow's method is the same as mine in essentials, but he does not employ the proportions which I believe to be important, and he dilutes his blood without allowing it to clot, which is much more difficult and less satisfactory. Lieutenant-Colonel Birt adds the corpuscles (human) at the first stage and the hæmolytic amboceptor subsequently. I experimented with this at the commencement of my researches, but abandoned it. There is a possible theoretical objection to it (the occasional presence of iso-hæmo-antibodies, which might, and I believe may, though rarely, cause spontaneous deviation of complement), and it makes the technique just a shade more complicated. Except for this, his method follows mine very closely.

### AUTHOR'S METHOD.

In my own modification[2] I prepare an emulsion of sensitised washed human corpuscles by adding 1 volume of corpuscles to 4 parts of heated immune serum from a rabbit which has been injected with human corpuscles. The strength of this serum is of some importance. It must be strong enough to sensitise the corpuscles to a trace of complement, and it must not be strong enough to clump them

[2] Vide THE LANCET, Sept. 3rd, 1910, p. 732.

instantly, so that they are shielded from the action of that substance. This is determined by experiment, and when the degree of dilution necessary is found the serum is diluted to that extent and placed in sterile ampoules. It gradually loses strength, so that it is advisable to make it a little stronger than is required in the first instance. Enough of this 20 per cent. emulsion of corpuscles to last for some twenty experiments is prepared; the mixture is incubated for a few minutes to allow of the linking-up of the amboceptor, and is then ready for use. For the test take 1 part of the serum to be examined and 4 parts of normal saline solution. The actual amount used is only about 5 cubic millimetres, and the various quantities are measured by means of a Wright's capillary pipette with marks indicating 1 and 4 units. Serum and saline are placed in a narrow tube in a water bath at 38° C. Next a mixture in identical proportions but made with diluted antigen is prepared, and placed side by side with the first. This is the test, the other the control. Other tubes of sera to be examined are prepared in the same way, and when these are done it will probably be time to complete the first test. For some extraordinary reason, which I have been unable to understand, it seems still to be the custom for workers at this reaction to allow the mixture to incubate for an hour or even longer at this stage. I showed last September that the combination takes place in five minutes or less at 38° C.; of course, if a large bulk of fluid is placed in an air-incubator it will take an appreciable length of time to reach this temperature, but with small amounts of fluid in a water-bath it is quite unnecessary to allow more. The second step is to add 1 part of the emulsion of sensitised corpuscles to each tube; if they have settled they must previously be mixed in well. If the balance between amboceptor be right the corpuscles in the control tube will be dissolved before they have time to settle, and if not they must be stirred once or twice, the tubes containing the actual test being stirred in a similar way. In a very few minutes the result can be read off. In a negative reaction both tubes show hæmolysis, complete or nearly so; in a positive one the first tube only will show hæmolysis, whilst in the latter the corpuscles will settle, leaving a colourless, supernatant fluid.

### Possible Quantitative Methods.

I have claimed as one of the advantages of this shortened method the fact that it allows quantitative estimations of the strength of the reaction to be made with the greatest ease; of the advantage of this I shall speak anon. Now there are three or more possible quantitative processes available. In the first, we take fixed amounts of serum and antigen, and see how much complement can be absorbed. I think this is the method usually employed, in a very rough way, when quantitative estimations are attempted. Two tubes are prepared, one containing twice as much guinea-pig serum as the other, and inhibition of hæmolysis in one tube and not in the other is regarded as a weak reaction, inhibition in both as a strong one. Sometimes more accuracy is attempted, and the exact number of hæmolytic doses absorbed is estimated. This is a very tedious process, and I have already urged theoretical objections to it.

Another principle is to keep the amount of complement constant, and to find the greatest dilution of serum which will just absorb it. This also is a practicable method, but it is more complicated than the method I am about to describe.

The process which I use (I claim no originality for it except in details) depends on the degree of dilution of the antigen. It has this practical advantage, that the series of dilutions of antigens can be prepared at the beginning of the experiment and are available for all the sera. Thus the amount of labour is much less than it would be if we had to prepare dilutions, it may be numerous, of each serum, and the chance of error is less.

### Standardisation of Antigen.

The first essential is, of course, a carefully standardised antigen. It might be thought that this would be essential for any method, but I do not think its importance is sufficiently emphasised in many of the descriptions of the process which are extant. Further, the method of standardising the extract which is described I believe to be wrong in principle. It should be compared with normal and not with syphilitic serum, and for this reason—the strength of syphilitic sera varies enormously, whereas that of normal sera is much more constant. Some syphilitic sera will give a positive reaction with antigen when the latter is diluted 300 times or more, so that it is obviously useless to attempt to standardise an unknown extract by an unknown serum and then work back and try to titrate the serum by the antigen. It is, of course, a great advantage to test the extract on as many known syphilitic sera as are available, but the criterion of its strength must be its action on the relatively constant normal serum. I employ, and should like to suggest as a standard, the use of an extract of such a strength that, when diluted to 10 times its volume, it exerts a definite inhibiting influence on a normal serum, but does not cause complete inhibition except in a small proportion of cases. Thus my last antigen was tested with six known non-syphilitic sera. All these gave complete hæmolysis in the controls, whereas when tested with a 1 in 10 dilution of the extract two gave hæmolysis of about half the total amount of blood, whilst the other four gave only strong traces of hæmolysis. With an extract of this strength some normal sera may give a complete reaction at 1 in 10, whereas others may give almost complete hæmolysis. A complete reaction with a dilution of 1 in 10, therefore, is without clinical significance; one at 1 in 20 is rarely seen, but when it is it is suggestive, and if met with, for instance, in a patient with a doubtful chancre, will usually be found to mark the beginning of a definite reaction. Complete inhibition at 1 in 30 is conclusive, but the reaction may go much higher than this.

I must repeat a warning on a subject touched on previously. It is necessary to bear in mind the fact that the extract may alter quite suddenly and without any warning. It may become either stronger or weaker. Thus I have seen a serum become four times as strong as it was previously in the course of a few days. Originally of the standard strength I have described, it suddenly became so strong as to give a positive reaction with all normal sera when diluted 1 in 40. On the other hand, it may become weaker—indeed, quite inert. This instability of the extract is one of the greatest difficulties the worker has to contend with, and is the chief reason why the reaction is not likely to become a consulting-room test. I do not know any means by which it can be avoided, but if the normal standard I have adopted be suggested, and if occasional tests of normal sera are made with a dilution of 1 in 10, it can easily be detected. If there is complete hæmolysis in these tubes the weakening of the serum may be suspected, whereas if they show little or no hæmolysis the extract has got stronger. In either case it is best to discard it and use fresh.

I prepare the extract from normal human heart-muscle as follows. The muscle is weighed, and 1 cubic centimetre of absolute alcohol added for each gramme of material. These are brayed together in a mortar, some pieces of glass being ground up with them. The mixture is heated to 60° C. for an hour. Next day the grinding and heating are repeated, and the mixture again allowed to stand for 24 hours, at the end of which time it is filtered and titrated with normal serum in the manner described. If it is too strong it may be diluted with 90 per cent. alcohol, but if it is too weak it is best to discard it and prepare some fresh. It is almost necessary to have several samples available in case one should suddenly become useless. I regard the care of the extract as the only real difficulty in the process.

### Author's Quantitative Method.

The actual technique of the quantitative determination of the strength of the reaction is as follows. First, a control test with normal saline solution (to make sure that there is abundance of complement) is made, and also a test with a dilution of extract at 1 in 30. If there is no hæmolysis in this tube it indicates a positive reaction. In this case a second test, at 1 in 100, is tried at once; if there is no hæmolysis in this still higher dilutions are taken, until the degree to which the extract must be diluted so that it does not inhibit hæmolysis altogether is found. The strength of the reaction is expressed by the weakest dilution with which there is no trace of hæmolysis. For example, if there was a trace of hæmolysis with a dilution of 1 in 150 and none with a dilution of 1 in 100 the serum would be said to give a reaction at 1 in 100. If there is hæmolysis at 1 in 30 the reaction is probably absent, but if present is extremely faint. I usually try also a dilution of 1 in 20. In a certain proportion of cases I try dilutions of 1 in 10, either with normal sera or

with sera which I have found to give a negative reaction at 1 in 20. This serves as a check on the extract. This should not be neglected; the few occasions on which I have obtained anomalous results have all been times when the extract has altered suddenly.

### ADVANTAGES OF A QUANTITATIVE METHOD.

The advantages of a quantitative method are numerous. It enables us to detect small traces of a reaction which would otherwise be overlooked. For instance, with a properly standardised extract I have never seen a complete reaction at 1 in 20 in any patient in whom syphilis could be excluded. At the same time, it is impossible to say that it might never occur, so that its significance is determined by the conditions of the case; for instance, it would render the diagnosis of syphilis in a case of tabes practically certain, but would be of much less importance in the case of a patient with a doubtful secondary rash and sore throat, in whom we should expect to get a much stronger reaction. Slight reactions—i.e., those at a dilution not greater than 1 in 30—are met with in very early cases, in very late cases, and in patients partially under the influence of mercury. In general, patients with well-marked syphilis give reaction at 1 in 75 or 1 in 100, and often much higher. In a general way I believe that a high reaction indicates a severe case, but a very much more important question is how the reaction behaves under treatment. In a few cases I have had the opportunity of watching the titre of the reaction gradually fall and disappear altogether, and it seems to me that a weakening reaction indicates that the treatment employed is suitable, and should be persevered with. In a single case I have witnessed the failure of mercury to influence the symptoms or to cause a fall in the strength of the reaction; the patient then had "606" and made a rapid recovery. In this case, as in another I had seen, the first effect of this latter drug was to cause a very rapid and marked rise in the strength of the reaction, which in one went up from 1 in 75 to 1 in 400. This rise was followed by a rapid fall, the reaction taking two months to disappear. In another case a weak reaction (1–30) disappeared in two days after an intravenous injection of "606."

Children and adults with hereditary syphilis as a rule give very strong reactions, and this must not be taken to indicate a bad prognosis. Occasionally, however, patients with slight indications of the hereditary disease may give mere traces of a reaction, and I think this may be taken to indicate, what has been denied, that the reaction may disappear with the progress of time in this class of cases.

Another advantage which quantitative work affords in the certainty of the diagnosis if a strong reaction is obtained. I should feel quite certain of the diagnosis, whatever the clinical symptoms or whatever the character of the case, if the serum gave a reaction at 1 in 100, and believe that with reactions like this (and they are the rule and not the exception in cases with manifest syphilis) the test is an absolute one.

### INTERPRETATION OF THE TEST.

Finally, let me lay down some rules for your guidance in making use of the reaction in diagnosis.

First, consider the stage of the disease, if syphilitic. If it is early in the primary stage a negative result means nothing, but if the supposed chancre has been present for six weeks or more you may expect to get a positive reaction, and its absence is of some weight as indicating the probability (it is not more than that) of a negative diagnosis. If the patient has what are secondaries, if syphilitic at all, the absence of the reaction is conclusive. If the disease is in a still later stage, but if there are lesions present and the disease, whatever it is, is progressive, then the absence of the reaction is *almost* conclusive proof that another diagnosis must be sought; the disease may be syphilis, but the chances are enormously against it.

If the patient is supposed to be in the later stages of syphilis, but there are no symptoms or lesions apparent, the question of cure arises. If the reaction is present, even if only slight, the patient is not cured. If there is no reaction the question is more difficult. I believe on the whole that you are justified in pronouncing him cured, but there is always the possibility that the case may be one of those rare ones which are supposed to occur in which no reaction is given at any time. If, however, you have previously examined the blood and have found the reaction, and then at a later date find it absent, the probability of cure is much more certain, always remembering the fact that mercury in itself inhibits the reaction.

Thus in a patient under mercury a positive reaction is conclusive—a negative reaction means nothing. In this case you must wait at least a month, and better for two, before pronouncing the patient cured. I believe a similar phenomenon occurs with "606," though here the explanation is probably different. At any rate, the patient should be examined some two months after the disappearance of the reaction to make sure that it has not recurred. If it has not the cure is probably complete.

Remember in all cases that a positive reaction indicates the advisability of continuing treatment. Thus, in the post- or para-syphilitic stages a reaction (in this case usually slight) may occur or may be absent. If present, I believe that antisyphilitic treatment is indicated, and may prevent the disease from going further, though it will not undo the harm that has been done, or prevent the gradual shrinking of scar tissue, &c.[3]

Remember that a person with congenital syphilis may give the reaction for life, and bear this in mind as a possible fallacy in interpreting such a result. In one of my cases at least the serum test seemed not to agree with the clinical diagnosis. The reaction was a strong one and was obtained by two other workers, and the mystery was not cleared up until the patient's family history was investigated. It is worthy of notice that if there is a question as to whether a case of syphilis is congenital or acquired, an examination of the blood of the mother will usually settle the difficulty, whilst an examination of the blood of the father will not necessarily do so.

It seems hardly necessary to mention the fact, but a positive Wassermann test tells us nothing as to any illness other than syphilis from which the patient may be suffering. The concomitance of syphilis and malignant disease is by no means uncommon, and though the Wassermann test will tell you in most cases whether a person has or has not the syphilitic infection, it affords no clue as to whether a given lump is a gumma or an epithelioma.

## THE MECHANICAL TREATMENT OF SPINAL CARIES.

BY H. J. GAUVAIN, M.A., B.C. CANTAB., M.R.C.S. ENG., L.R.C.P. LOND.,

MEDICAL SUPERINTENDENT, LORD MAYOR TRELOAR CRIPPLES' HOSPITAL AND COLLEGE, ALTON, HANTS.

### *Splints and Hyper-extension in Spinal Caries.*

AMONGST the commoner diseases prevalent in this country the treatment of few, perhaps, has been so neglected as tuberculous disease of the spine. This is the more a reproach as the disease was first effectively studied by one of our greatest English surgeons, Pott, and his name has been universally given to the condition. The reasons for this neglect are perhaps not far to seek. The course of the disease is a long one; conservative treatment, the most satisfactory and indeed the only treatment that can be seriously considered for the bulk of the cases, is slow and tedious. But perhaps the most potent cause for this neglect is the fact that, outside our infirmaries, there are few institutions in this country able to devote a sufficiently large number of beds for a sufficiently long period to enable the disease to be really efficiently studied and treated. Hence it is that the condition, though very amenable to treatment, has been regarded with feelings almost of hopelessness. Very rarely are careful attempts made to prevent the onset of deformity or to correct deformity already existing, and though the prognosis as regards cure is not considered bad, yet deformity and severe crippling are by many regarded almost as inevitable.

At the hospital at Alton, in Hampshire, established by Sir William Treloar in September 1908, a very considerable number of beds are occupied by cripples suffering from tuberculous disease of the spine. A patient once admitted is not discharged until there is reasonable

[3] In my first 12 cases of tabes I got a positive reaction in all. This was mere chance, and since then I have got about 65 per cent. of positive results, much the same as other observers.

evidence that the disease is arrested or cured. The treatment is conducted under ideal conditions and every endeavour is made not only to cure the patient, but also to prevent or correct deformity. Before outlining the means by which deformity may be prevented or arrested, it is desirable to consider the nature of the deformity and the factors which produce it. Tuberculous caries commonly affects the bodies of the vertebræ. Other parts of the vertebræ may be attacked, but for the purpose of this paper consideration will be directed to the commonest lesion—caries of the body. The extent of the caries varies from a small and relatively insignificant lesion to an extensive one affecting several contiguous vertebral bodies with their corresponding intervertebral discs, and the ligaments and structures adjacent. In progressive and untreated cases the result primarily is a tendency for the spine to bend forward above the lesion and to a less extent below the lesion, forming at the lesion the so-called angular curvature; and secondarily deformity of other parts owing to displacement, compensation, or muscular spasm or contraction. The degree of deformity is very variable and depends on numerous factors, of which may be enumerated the position in the spine of the tuberculous lesion, its extent, its direction of progress, the effect of treatment, age of patient, amount of muscular spasm, &c.

The causes of the primary deformity are: (1) Destruction of the attacked bone; (2) the effect of gravity acting upon the weakened spine; (3) muscular spasm secondary to the inflammatory process; and (4) alteration in intermuscular balance, leading to certain muscles acting at an unduly great or diminished mechanical advantage, and ultimately becoming permanently contracted or attenuated. The first two causes are obvious and well recognised, but the latter two, while being of the highest importance, have received little attention. It must be remembered that the lesion is first of all an inflammatory one, and that it is a generally accepted rule that in the treatment of an inflammatory lesion rest is of the first importance. Therefore all acute cases of spinal caries should not only be at rest but be at rest in the recumbent position; and, furthermore, to rest completely the inflamed part immobilisation of that part is necessary to fulfil the requirement demanded. Rest in the recumbent position will at once abolish one of the factors causing the deformity—viz., the action of gravity upon the weakened spine—for in this position pressure of superincumbent weight is removed entirely, while if the patient is immobilised the strain of use is abolished.

The next point to be most strongly emphasised—and the more so because it is in spinal caries so little considered—is the effect of muscular spasm. Muscular spasm and consequent spinal rigidity manifests itself very early in the course of the disease and is one of the most valuable aids to early diagnosis, frequently appearing some considerable time before there is any evidence of angular curvature. It is primarily protective, being nature's way of securing immobility to the affected part, but the cost of this immobility to the patient is heavy and can be altogether avoided. Unchecked it produces much pain and may actually aggravate and promote the spread of the disease. Artificial immobility, properly applied, avoids these drawbacks. Professor Howard Marsh [1] very clearly describes the evils of unchecked muscular spasm: "All will accept the general proposition that rest is essential in the treatment of inflammatory diseases of the joints. Yet there are some points which require to be insisted upon in order that this principle may be adequately carried out. The first relates to the injury produced by reflex contraction of the surrounding muscles. This reflex contraction is present in the case of all the articulations." It produces "interosseous pressure which is mischievous not only in its immediate effect on the ends of the bones, but because, by giving rise to reflex irritation, it tends to maintain and aggravate spasm in the surrounding muscles. Indeed, these two conditions of interosseous pressure and muscular spasm act and react on each other and so concur to promote the advance of the disease." The muscular spasm especially affects those muscles adjacent to the focus of the disease. The contraction of the muscles alone, even when the patient is recumbent and when the action of gravity in the production of deformity is removed, may of itself, and frequently does, cause deformity. The eroded vertebral body under the constant strain of its investing irritated muscles is gradually compressed and at length gives way. Deformity once commenced proceeds more rapidly as the mechanical advantage under which the anterior spinal muscles act becomes more pronounced, while the opposition offered by the posterior muscles simultaneously decreases. "Normally, when the body is erect, there is a proper adjustment or balance between the bones, the joint structures and the muscles, so that the weight is borne easily without any special strain upon any one part or to any one structure. As soon, however, as the body bends forward, as it must at the seat of the disease, the posterior muscles, because obliged to pull round the angle of the knuckle, work at a distinct disadvantage, and the balance between the extensors and flexors, which is nature's protection against deformity, is lost. The anterior muscles improperly antagonised draw the body forward." [2] The muscles once contracted, if left to themselves, do not relax, but remain permanently shortened. Even if the disease does become arrested they still anchor down the bent and by this time commonly ankylosed spine, and if the patient is a child the evil results in subsequent growth may become still more apparent, for not only is the deformity maintained but other structures in the vicinity become more displaced, embarrassed, and more distorted. In dorsal caries the baneful effects of this are particularly apparent.

From consideration of the preceding statements it follows that in the treatment of acute spinal caries general rest should be enforced, absolute rest to the affected part is desirable, deformity should if possible be prevented, interosseous pressure at the site of the disease avoided, and muscular spasm overcome. These desiderata may all be obtained by keeping the patient recumbent, immobilised, and hyper-extended, the hyper-extension being in some cases aided by traction extension.

I now turn to the details of the apparatus employed designed to meet those requirements in the treatment of spinal caries which I have emphasised. Many varieties of spinal boards have been described, and it is impossible in this paper to consider all these or to weigh their respective advantages or drawbacks, but one which appears to be peculiarly suitable for the treatment of spinal caries while the patient is in the recumbent position is that used at the Maritime Hospital, Berck-sur-Mer.[3] This board is the model which I take for those employed at Alton, but I have altered the board in various ways, and I venture to think I have made it more generally suitable for the treatment of these patients. The board as used at Alton consists of an oblong tray made of strong but light wood. The length should be from 12 to 18 inches longer than the patient and the width about 8 inches greater than his greatest width. The sides of the board are about the same height as an ordinary Phelps box, roughly 3 to 4 inches, with the exception of the foot end, which is raised to a height of from 15 to 18 inches and thereby takes away from the patient's feet the weight of the bedclothes and tends to prevent the onset of foot-drop. The bottom of the board is perforated with numerous holes to admit ample ventilation of the mattress. The corners are bound with sheet-iron angle pieces, which, while adding greatly to the strength of the apparatus, do not unduly increase its weight. Across the board is placed a piece of wood of suitable height, usually 2 to 3 or 4 inches, and of about the same width, which stretches from one side of the board to the other and is designed to be placed immediately under the most prominent part of the angular curvature. It is fixed by means of two iron pins which serve a double purpose—(1) to retain the cross-piece in position, and (2) to indicate at a glance where on the patient the angular curvature is. A firm pillow, if fixed, forms a suitable substitute for the wooden cross-piece. A well-prepared horsehair mattress occupies the tray over the cross-piece and on it the patient reclines. On the head and foot ends of the board are slits cut for the hands to facilitate its transport. At the head end of the board two pieces of strong elastic webbing 1 inch wide and about 6 inches long are attached, and to these a bridle can be buckled when head extension is desired. At the foot end, which, as previously described, is raised to prevent foot-drop, are two longitudinal slits

# An Address

ON

# SOME MEDIASTINAL AFFECTIONS.

*Delivered at the Medical Graduates' College and Policlinic on Jan. 30th, 1911,*

BY PERCY KIDD, M.D. OXON., F.R.C.P. LOND.,

PHYSICIAN TO THE LONDON HOSPITAL; CONSULTING PHYSICIAN TO THE HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON, AND TO KING EDWARD VII. SANATORIUM.

GENTLEMEN,—It is not my intention on the present occasion to attempt to deal with the general topic of mediastinal tumours. I wish first to describe briefly certain unusual examples of mediastinal disease, and secondly to discuss some points in the clinical symptoms and diagnosis of tuberculous mediastinal glands.

## I.—UNCOMMON CASES OF MEDIASTINAL DISEASE.

CASE 1. *Substernal thyroid tumour simulating a mediastinal new growth; operation; recovery.*—The patient was admitted into the London Hospital in February, 1906, as a case of mediastinal tumour. For some four years he had suffered from difficulty of breathing. Treatment had given some relief until two weeks before admission, when his breathing became much worse. Two months previously to admission a lump in the neck was first noticed by his medical attendant. The patient was a dark man, of Hebrew race, with an anxious expression, but not obviously wasted. There was slight stridor, mainly inspiratory. The superficial veins of the neck and chest were distended. On coughing a large swelling appeared in the neck above the clavicles, more on the left side, suddenly disappearing when coughing ceased. No lump was felt behind the clavicles. The lungs were hyper-resonant on percussion and the breath sounds were universally weak. There was no dulness over the sternum. The heart was normal. The larynx was healthy; no paralysis of vocal cords, and no dysphagia.

The long history and the absence of wasting seemed to exclude malignant disease, though the evidence of mediastinal pressure was very clear. The diagnosis suggested was substernal thyroid gland. The swelling above the clavicles on coughing was attributed to emphysematous bulging of the apices of the lungs. My colleague, Mr. James Sherren, examined the case, and pointed out that the swelling which appeared in the neck on coughing was dull to percussion, and he suggested that it was due to a moveable substernal thyroid tumour. Radiograms showed a fusiform shadow behind the sternum running up towards the neck. Mr. Hurry Fenwick subsequently saw the patient and agreed to attempt the removal of the tumour.

On March 5th, under chloroform, an incision was made along the upper border of the left clavicle in its outer half. From the inner end of this incision another was carried up and out to the anterior border of the trapezius. The veins were very large and bled freely and had to be ligatured. The platysma and omohyoid (posterior belly) were cut through and a dissection made on to the sheath of the subclavian vessels. No signs of the lump were found. The patient was made to cough and the lump was found to the inner side of the wound. The incision along the line of the clavicle was carried further and more vessels were caught and ligatured, first the muscular head and then the sternal head of the sterno-mastoid muscle had to be cut through. The lump was then found and exposed. A retractor was put on to hold back the soft structures and the swelling was grasped by tenaculum forceps and pulled out. On puncture yellow cystic fluid escaped. The lump, now smaller, was pulled on and eventually shelled out of its bed. It was much larger than at first suspected and was about the size of a large William pear. There were no adhesions. The tumour was continuous with the isthmus of the thyroid gland. The junction was cut through, the vessels ligatured, and the surface cauterised. The cavity occupied by the tumour reached down into the thorax behind the arch of the aorta. A drainage-tube was inserted in the cavity. The tumour proved to be an encapsulated adenoma. The wound healed fairly well, but some suppuration took place.

The patient was discharged on March 30th. When I saw him a few weeks later the wound had healed and no abnormal physical signs could be detected. The patient was completely relieved of all his symptoms. I have given the full surgical notes of Mr. Hurry Fenwick's operation as the case is an unusual and instructive one, and the results were highly satisfactory.

CASE 2. *Mediastinal cyst (? dermoid).*—The patient, who was 20 years of age, had suffered from a dry cough from January to Easter, 1891, when he was suddenly seized with sharp pain in the left side and shortness of breath. Signs of pleural effusion developed and he was tapped, a quart of clear yellow fluid being withdrawn. A week later he was aspirated again, the result being a tumblerful of turbid fluid with flakes floating in it. Since then he had dragging pain on raising the left arm, and dyspnœa. In August, 1891, a swelling appeared in the upper part of the subcostal angle. I saw the patient at the Brompton Hospital as an out-patient in October, and he was admitted under my care through the kindness of my colleague, Dr. F. T. Roberts. Physical examination showed dulness and signs of fluid on the left side from the second space in front and the spine of the scapula behind to the base. The heart was displaced to the right of the sternum. On the right side in front from the clavicle to the third space there was a vertical strip of dulness extending from the middle line of the sternum outwards to the right for 1½ inches. Immediately below the ensiform cartilage there was a rounded, slightly pulsating elastic swelling. The signs were somewhat puzzling. For although the evidence of fluid in the left pleura was unmistakeable, the patch of dulness to the right of the upper part of the sternum and the epigastric tumour were difficult to explain. The possibility of an encysted mediastinal empyema was suggested.

On Oct. 15th the patient was aspirated by Mr. R. J. Godlee in the eighth space in the scapular line, and 65 ounces of dark blood-stained fluid were drawn off. Microscopically red blood corpuscles, leucocytes, and spherical epithelial cells with large nuclei and granular débris were found. The dulness on the left side diminished, but the epigastric swelling and the patch of dulness to the right of the sternum persisted. I will now quote Mr. Godlee's account of the subsequent history of the case.[1]

> On Nov. 28th an incision was made into the epigastric swelling which was becoming more tense, and a cavity was opened containing a considerable quantity (6 or 7 ounces) of brown purulent fluid something like that previously extracted from the side, floating in which were numerous small rounded masses of a brilliant chrome-yellow pultaceous material, looking like the yellow palm oil used for lubricating the wheels of railway carriages. The cavity extended upwards behind the sternum, and on a subsequent occasion I endeavoured to discover its upper limit by making a hole through the sternum. The finger, however, was found to be amongst the large vessels in the superior mediastinum and I did not venture to go any further. An elaborate analysis of this fatty material was made by Dr. Halliburton, but it threw no light on the case. We never found any of the usual contents of dermoid cysts and I do not therefore know whether the case should be placed here [i.e., chapter Dermoid Cysts]; but I am at a loss for any other explanation of it. The yellow material continued to escape for a considerable time and ultimately the sinus closed. It remained healed for some time, but subsequently a small ulcer formed at the top of the sternum, which, after discharging for some months, finally healed

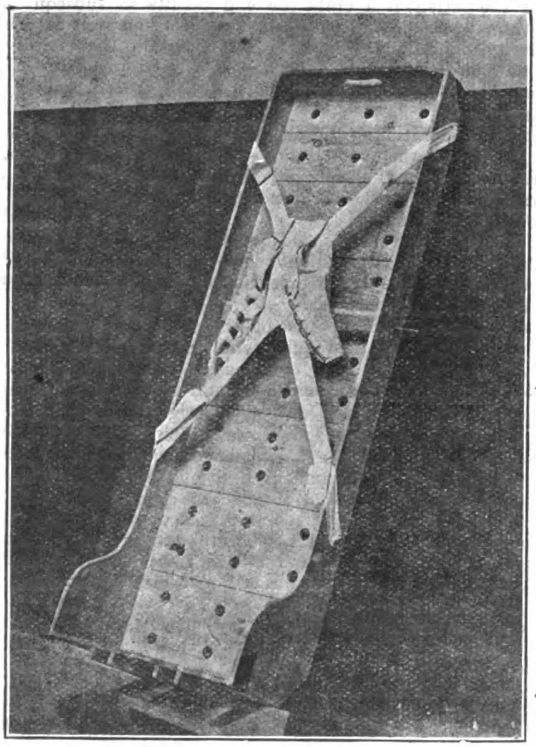
I saw the patient myself in 1897—i.e., about five years after the operation—when he was in excellent health. There was a small scar just above the right sterno-clavicular joint, and deep scars over the lower end of the sternum and epigastrium in the site of the two operations. With the exception of slight deficiency of movement on the left side of the chest there were no abnormal physical signs.

CASE 3. *Mediastinal abscess perforating the trachea and œsophagus and causing subcutaneous emphysema and cellulitis.*—The patient, a man aged 37 years, was admitted into the London Hospital on Oct. 4th, 1900. He had been taken ill seven days previously with a shivering fit and sweating, and shortly afterwards he had noticed a red swelling in the neck. The swelling had been much worse a few days previously to admission, diminishing suddenly after spitting up much phlegm. On admission the patient was cyanosed, and the skin of the lower part of the neck was congested and boggy, and emphysematous crackling was detected. The pulse was 138, the respirations were 42, and the temperature was 100·8° F. There was dulness to percussion over the lower

[1] Fowler and Godlee: Diseases of the Lungs, p. 698.

through which the cords of a leg extension can be passed over a suitable pulley. This pulley is fixed to two perforated upright pieces of wood attached to the board on each side of each longitudinal slit, and these are so arranged that between them an upright extension rod can be inserted if there is much flexion, and if at the commencement of treatment the leg cannot be sufficiently extended to allow it to be drawn directly in line with the trunk. As a matter of convenience it is usually desirable to fit into these extension poles a triangular frame of wood terminated by a pulley which will carry the extension well beyond the foot of the bed and allow the extension cord to hang free. The patient is fixed on this board in a very simple and effectual manner. A jacket composed of stout jean fitted accurately to his body and preferably stiffened with whale-bone encases the patient. On the back of the jacket two strips of webbing are

FIG. 1.



Spinal board.

let in, which strips cross each other as a St. Andrew's cross, and these are buckled to the sides of the board and effectually prevent the patient from moving in any direction and keep him in the exact position which has been decided upon as desirable. The jacket should be laced and buckled over the front of the patient, as in the case of a child mere buckling will not prevent the patient from undoing his straps and himself altering his position. Children are somewhat puzzled if in addition to the buckles the jacket is laced, and this combination is usually sufficient to prevent them altering the adjustment.

This board has numerous advantages. It is extremely simple, efficacious, portable, convenient in nursing, hygienic, and comfortable for the patient. The bed-pan can easily be administered without the patient's position being in any way disturbed, and if desired the patient can be tilted out of the horizontal position, but in this case an addition should be made to the jacket which will be described later. It will be at once seen that extension can be made from the head or the legs to any extent required without the board being necessarily tilted, as the method of fixing the patient prevents him from sliding out of the desired position. In cases of cervical caries a bridle is fixed on the head and attached to the elastic straps already referred to. This bridle should be especially constructed and adjusted with great care. I am in the habit of making it of webbing, and the particular form of bridle employed has the following features: the chin strap has a diamond-shaped aperture in which the chin can be inserted and fixed, or better is made of leather moulded on to a cast of the chin; the occipital strap meets the chin strap at a point between the eye and the ear on each side, being permanently attached on one side and buckled on the other. From this angle of union a straight strap on each side passes to the elastic extension bands, and these traction bands are prevented from slipping by another strip of webbing attached to them and which passes round the head, behind over the most prominent part of the occiput and in front across the forehead just above the eyes. The object of having a bridle fixed in this way will become apparent if the method in which the extension acts is considered. The centre of gravity of the head lies roughly in a line between the eye and the ear. The more anterior the point of traction be on this line the more hyper-extended the head will become, and the nearer the ear the point of traction may be the more will the head tend to flex. If, then, the particular degree of hyper-extension be decided upon and that point be always rigidly adhered to, the rest which will be given to the diseased cervical spine will be most effectual and an approximation of immobilisation be obtained. To prevent lateral movements of the head either side straps may be applied, or else, as is more commonly done, a sand bag on each side secures the desired fixation.

In cases of dorsal caries, particularly upper dorsal caries, angular curvature produces a very marked and unsightly deformity. The deformity here is of two kinds: (1) the primary deformity due to the curvature itself and (2) the secondary deformity induced in the bony thorax and which is entirely the result of displacement produced by the alteration in the contour of the spine. If deformity of the spine is prevented, the secondary deformity does not occur. It is desirable in cases of upper dorsal curvature to remember that the scapulæ themselves and the muscles attached thereto may prevent the best results being obtained by hyper-extension, and it is therefore often desirable to place in the jacket which has already been described appropriate padding under the curvature and between the shoulder-blades to increase the hyper-extension which would be produced by the cross-piece alone, but which, if the cross-piece alone were employed, could not act to best mechanical advantage.

In cases of lower dorsal or lumbar caries psoas spasm is an additional factor which must often be considered, and this can be best overcome by leg extension, which again by the method of fixing the patient can be easily applied without discomfort and without the board being removed from the horizontal position.

In cases where the disease is active and where there is much reflex irritation of the muscles about the spine simple hyper-extension is sometimes not sufficient, and head and leg extension combined will be necessary to overcome the spasm of the muscles and prevent increase of deformity resulting from muscular spasm, but this extra extension very rarely has to be maintained for any considerable period. Three weeks of combined head and leg extension is usually sufficient completely to abolish spasm of the muscles—at any rate, spasm of a sufficient degree to cause deformity.

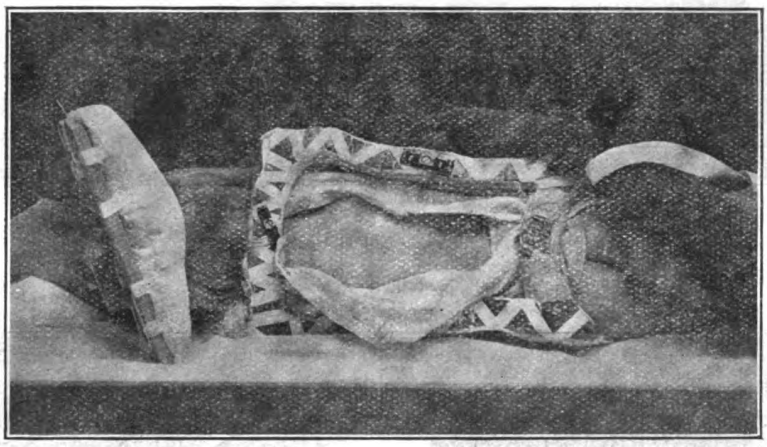
The board just described, while extremely efficacious and of the very greatest value, has, nevertheless, some disadvantages to which I will now allude, and these disadvantages, though apparently not serious, are still sufficient to make it desirable to design some other method of mechanical treatment. In the first place, it must be remembered that in a patient with spinal caries strapped in one position with considerable pressure acting on the angular curvature, bedsores may occur unless the greatest care be taken, and to prevent the onset of bedsores it will be found desirable in the majority of cases to attend to the patient's back every four or at the most every six hours. It is my practice to have the child turned on his side at these intervals and the back thoroughly washed, powdered, and massaged. If this treatment be assiduously undertaken bedsores should not occur. But it will be at once seen that the necessity for this movement is a great disadvantage—(1) because the spine is not maintained in a state of rigid immobility, and the movement may retard the arrest of the

disease or may even provoke a new spread of the inflammation; and (2) because it is almost impossible to ensure that after the child is replaced in his jacket the adjustments will be as perfect as is desired and the apex of the curvature occupy the summit of the convexity on the board. It may seem that these objections are not of the first importance, but in practice I find that they undoubtedly do occur and that they are a source of danger. It is quite easy for the nurse to replace the child in such a position that the curvature is a little above or a little below the cross-piece, and in that case not only is the deformity not diminished, but it may even be increased. Another point to be remembered is that some distension of the child's abdomen with flatus will necessitate the loosening of the jacket and may allow the child to somewhat shift his position.

To overcome the above disadvantages I have been in the habit of employing a splint which I have especially designed and to which the name of "the back-door splint" has been applied. Each spinal splint is made especially for each individual case.

*Measurement of the splint.*—The patient is stretched on his back on a piece of paper, the head is held by one assistant and the legs by another, and the contour of the trunk is traced out. The splint should be a shade smaller than the contour of the trunk. The bottom of the splint should be just above the natal cleft. The tracing is then cut out and a piece of beechwood cut to exactly a similar size. Well-seasoned beech is especially chosen because experiment has shown that it is very strong, that it does not warp readily, and it has the additional advantage of being cheap. The outer part of this is cut away 1 inch from the periphery all round, forming an outer frame. This is covered with sheet iron screwed to the frame, and forms a strong and rigid framework. The iron is then lacquered to prevent it rusting when subjected to the heat and moisture of the body. The inner part or back door which fits into the outer frame accurately is pared down a little so that it can be removed and replaced with great ease, and is perforated with holes for a double purpose—both to ventilate and to assist in fixing the padding which is later to be applied to it.

FIG. 2.



Back-door splint with patient. The splint is so designed that the patient may be permanently immobilised and hyper-extended while the back is readily accessible. The back door is easily removeable and may be repadded as circumstances require. On this splint the patient can lie in comfort for an indefinite period, and increasing deformity is impossible.

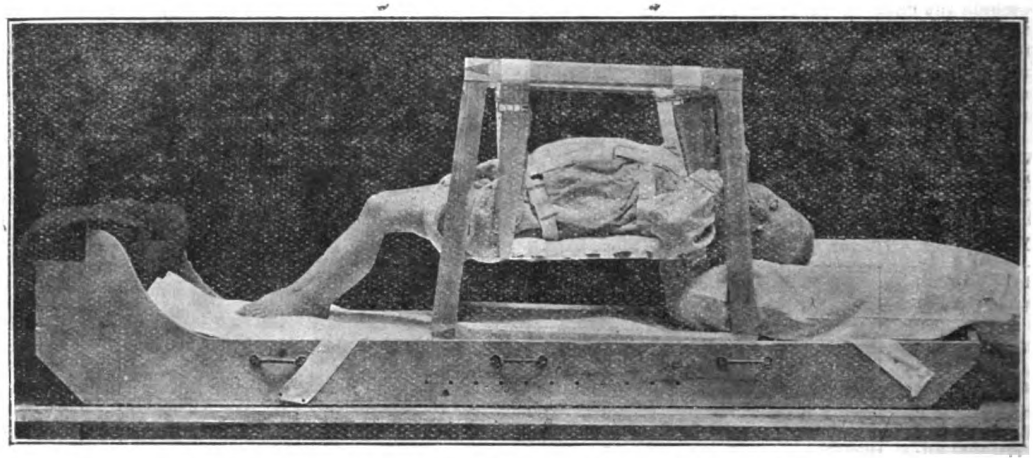
*The padded outer frame and back door.*—The outer frame is padded evenly all round, but especial care must be taken in padding that part which will come in contact with the sacrum. The padding should be perfectly even, and the best material to employ is animal wool because this never cakes and has a springiness and elasticity which make it peculiarly suitable for this purpose. The padding is firmly bound down to the splint by splint linen, and should be covered on the lower part with jaconet to prevent it being soiled or saturated if the patient is not able properly to control his evacuations. The back door has on the lower aspect a suitable handle which facilitates its introduction or removal from the outer frame. It is kept in position by four small clips which are attached to the outer frame. The surface of the back door next to the body is also padded thickly with animal wool, and this padding should be especially thick and firm at the site of the disease, so that due hyper-extension of the spine may be obtained. It will be found convenient to use tape in the fixing of the splint linen instead of ordinary thread, as with the tape the padding can be made more secure and much more durable. The patient is fixed on to this splint by means either of a jacket or by webbing. Webbing is simpler to apply and is better in warm weather, but the jacket is neat and gives the apparatus a more finished appearance when in use. If a jacket is employed it will be found most convenient to attach it to the outer frame on its inner side, and the jacket should be made in two pieces, each in duplicate, so that should it become soiled the soiled portion can be immediately removed and replaced. In any case it would be desirable to remove the jacket at intervals so that it may be cleaned—about once monthly is commonly sufficient. To facilitate the removal it will be found convenient to employ patent placket fasteners. By the use of these the jacket can be removed with the greatest ease and speed and be instantly replaced. The jacket should be strapped and laced over the front of the patient, as in the manner described previously. Should webbing be used in place of the jacket a piece of webbing should come over each shoulder. Two pieces should come round the trunk and all should be fixed to the inner side of the outer frame of the splint. They should be buckled appropriately on the front of the trunk. It will be found that by employing a splint of this nature the patient's back can be attended to without the patient being moved, and with the very greatest ease. The patient's shirt should open at the back, as in the illustration. (Fig. 2.) The patient can then have his back washed, powdered, and massaged at the necessary intervals, and soon is so little disturbed in the process that he does not even wake up when this is being undertaken by the nurse. Moreover, he is permanently immobilised in that position which has been decided upon as the best one for his requirements. There is no possibility of a mistake on the nurse's part in the readjustment of the child, and while he is turned his spine is still held rigidly in position by the outer frame. Once a day the jacket is unlaced or the webbing unbuckled and the child is washed without even being removed from the splint. In this way he may be kept for an indefinite period if desired without altering the contour of the spine. This description indicates the principles of the back-door splint, and I will now further describe its use for special conditions of the spine.

In cases of cervical caries either a simple bridle extension, as already described, may be employed or, better, the outer framework is prolonged on each side of the head and is terminated by an upright iron bar to which the bridle is attached by the elastic extension already described. The child is then turned as a whole when his back requires attention. It will be seen that this prevents any danger of injury in cervical caries and altogether prevents the possibility of those appalling disasters which have been reported when the transverse ligament of the atlas vertebra is affected.

In cases of dorsal and lumbar caries additional hyper-extension may be obtained in two ways: (1) either by mounting the outer frame of the splint on short legs; or (2) by suspending the outer frame. The latter method I shall describe first. Here, what we speak of as the swinging back-door splint is conveniently employed. The illustration appended will explain most graphically the nature of this splint. The idea of swinging a patient with dorsal

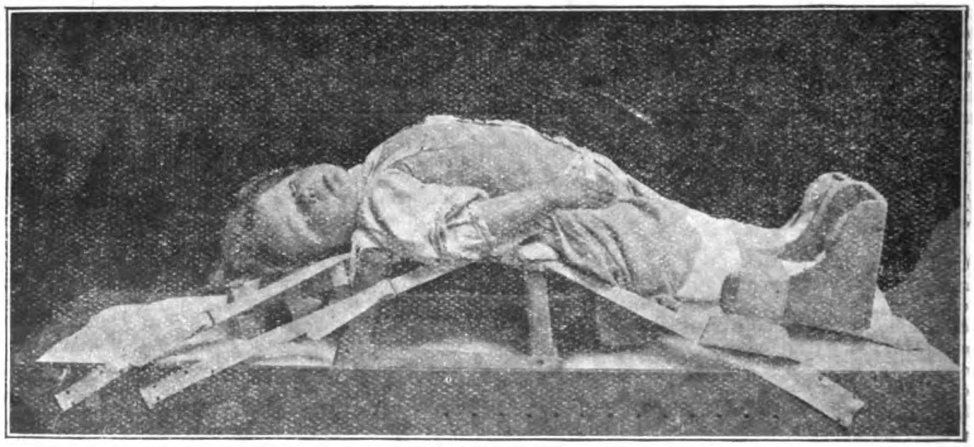
caries is by no means a new one and had been attempted long ago by Rauchfuss.[4] He, however, simply swung the patient in a canvas hammock, and this method had many drawbacks, inasmuch as the patient was not adequately immobilised, attention to the back could not be given easily, and there was some danger of lateral compression of the thorax. In the combination recommended here it will be seen that there is a rigid support for the back, the back can be easily reached and attended to without interfering with that rigid support, the patient is absolutely immobile, and the thorax is not compressed, nor is respiration or digestion in any way impeded. The proper hyper-extension is obtained, and the partial weight of the legs and head is of the utmost value in overcoming muscular spasm.

FIG. 3.



Swinging back-door splint. The head and legs here form a natural means of extension.

FIG. 4.



Wheelbarrow splint, especially indicated where there is spasm of the psoas muscles or psoas abscess.

When the disease is in the lower dorsal, dorso-lumbar, or lumbar regions, and when spasm of the psoas muscles occurs, it will be found perhaps desirable to immobilise the legs, and for this purpose the splint on legs, already alluded to, has been designed. This has been named the "wheelbarrow" splint. The illustration here given will best describe this splint. It will be seen that the outer frame of the back-door splint is supported on four legs, and that the legs themselves of the patient are fixed to back splints which are attached to the frame by a special hinge so designed that the legs cannot flex, can hyper-extend to any degree desired, can abduct or adduct (so that the bed-pan can be applied with ease and the child be attended to with comfort), cannot invert or evert. Extension may be applied to both legs with the greatest ease, and it is recommended that this extension be applied with the assistance of the special foot-splint figured, which is a modification of one used at Berck-sur-Mer. It will be seen that the extension strapping is attached to this foot-splint, and the weight comes on the foot-splint itself. With this contrivance perfect fixation can be secured with comfort to the patient. The head may either be supported by the pillow, which should be at a lower level than the splint, or by an extension of the splint upwards, and the latter is usually employed, as the head is then always at the same level and a constant pull by the weight of the head is ensured. Uncomfortable as it may seem, neither this nor the swinging back door-splint is objected to by the patient. Head extension can of course be applied by the aid of the bridle as before mentioned.

One small point may be here mentioned which does not seem to attract attention, but is worth consideration, especially in an institution where many spinal cases are under treatment. Spinal boards of any description whatever employed are commonly put on ordinary beds, and it will be noticed that this involves not only the bed necessary for the spinal board but also the mattress and accessories required for the bed. Further, the bed is invariably so low

[4] Ménard: Loc. cit.

that if many cases have to be treated undue strain is put on the nurse in tending the child by the constant stooping which the low position of the bed demands. To avoid this I have substituted for the bed commonly employed a special stand which is simple in construction and adapted specially for the requirements of the special cases here described. The stand can easily be constructed by any intelligent carpenter assisted by a blacksmith. Its legs are of ordinary gas-piping cut to a height of some three feet, and on these legs is mounted a wooden frame on which the board is placed. The board is then at a convenient height for the patient to be attended to without strain being put on the attendant, and is found convenient in every way from the nurse's standpoint. The patient's mattress is much more easily ventilated and the patient's comfort is thereby increased. A special covering made to fit the board is placed over the patient and board and makes it impossible for the clothes to fall from the patient. The greater height at which he is placed usually results in the patient being nearer an open window and increases the amount of fresh air he can receive. Dust and dirt can find no place under the stand and that is a consideration which is especially desirable to bear in mind in a private house. It will also be noticed that the amount of bedding and blankets required is much decreased, and this is of importance in the economical working of an institution both from the point of view of first cost, where the save in horsehair for mattresses and in bedding materials is thereby decreased, and also in cost of upkeep as the amount which is sent to the laundry is sensibly diminished.

FIG. 5.

Stand as used for reading and feeding.

Granted that there is no reason why the patient should be kept lying in the recumbent position, before he is allowed to assume the erect attitude the length of time he has been recumbent should be remembered, for it is obvious that if a patient has been in a horizontal position for a considerable period any change from that position to the vertical will be associated with alterations in the blood pressure, and if this alteration be not borne in mind consequences which may be somewhat alarming may ensue It is my practice never to allow a patient to be suddenly permitted to assume the erect attitude, and to permit this transition to take place conveniently he is commonly placed on the stand which is here figured and which may indeed, if desired, be employed throughout the whole treatment.

The essentials in this stand are that the patient at will may occupy any position, either horizontal or vertical, or at any intermediate angle. This alteration is very simply effected by merely turning a handle which governs a screw fitted into the cogs of a semicircular piece of brass which will be seen attached to the under-surface of the spinal board. The patient when tilted in this way should have, at any rate in the case of an adult or large child, additional support to that given by the jacket before described, for while this jacket alone will hold him firmly, yet without other assistance it may cause him undue and unnecessary discomfort. It will therefore be found desirable to have two pieces of webbing passing longitudinally down the board from the head end and let into the back of the spinal jacket on either side of the spine. These pieces are continued under the crutch and are there padded with a small pad of animal wool and covered with jaconet, and this pad is so adjusted that it will press on each of the tuber ischii. The webbing continued from the crutch passes over the front of the patient and is strapped to the board on each side at about the level of the nipple. This simple contrivance will effectually and comfortably support the patient even in the vertical position and will not in any way bring undue pressure to bear upon his spinal lesion provided he has in the first place been so placed on his board that the spine is sufficiently hyper-extended. In many cases it is permissible to allow the patient to rest on a seat, which can be suitably adjusted to the spinal board. This is permissible when there has been no spasm of the psoas muscle or when there have been no complications, such as gluteal abscesses. It will be at once seen that when the patient is in this position he has the great advantage of seeing surrounding objects with ease, and when a suitable book-rest is adjusted to the board he can read and feed himself with comfort in the natural position. Such a contrivance will be found of the very greatest service to these patients, who are so helpless and so debarred from simple pleasures and conveniences, and it will be of particular value in the case of children, who can thereby continue their education within reasonable limits without in any way complicating or interfering with the treatment which is being applied. It will be noted that this tilting stand is mounted on wheels and can easily be wheeled out of the ward or room into the open air, and in fact can be wheeled anywhere as easily as could a bath-chair, and the delight which this possibility of change of scene gives to the child is of value and assistance in the treatment. He can be conveniently and expeditiously removed out of doors and attended to throughout the day, and this in itself is, as will be readily seen, of the greatest value.

The great benefits which resulted from the alteration from the horizontal to a more or less vertical position suggested that where the patient was suffering from a sinus it would be an advantage to place the patient in that position where the sinus could be best drained, provided the essentials already indicated were maintained, and the stand illustrated may be obtained to satisfy this requirement. On it the patient can be fixed in any desired position, at any angle in any plane.

In this paper I discuss mechanical treatment during recumbency only. Mechanical treatment after the abandonment of the recumbent position will be discussed at another time.

Alton, Hants.

WORKMEN'S COMPENSATION ACT, 1906.—The Home Office has published a list of the names, addresses, and districts of certifying factory surgeons in England and Wales. The duties of the certifying surgeon have since 1907 been extended to industries outside the Factory Act by the provisions in the Workmen's Compensation Act with respect to compensation for industrial disease, under which a worker in those industries before he can claim compensation for disease has to obtain a certificate from the certifying surgeon; and this list has been prepared as a ready means of reference for workers and their representatives desiring to ascertain the name and address of the certifying surgeon to whom application must be made in any particular case. (Persons employed in factories or workshops can always ascertain the name and address of the certifying surgeon by reference to the abstract posted up in the works.) The list is published at 1s., and can be obtained, either directly or through any bookseller, from Messrs. Wyman and Sons, Limited, Fetter-lane, London, E.C. Similar lists for Scotland and Ireland will be published in due course.

# THE EDUCATION OF THE DEAF:

## ITS PRESENT STATE IN ENGLAND, WITH SUGGESTIONS AS TO ITS FUTURE MODIFICATIONS AND DEVELOPMENT.

BY MACLEOD YEARSLEY, F.R.C.S. ENG.,

SENIOR SURGEON TO THE ROYAL EAR HOSPITAL; MEDICAL INSPECTOR OF LONDON COUNTY COUNCIL DEAF SCHOOLS; LECTURER TO THE LONDON TRAINING COLLEGES FOR TEACHERS OF THE DEAF; EXAMINER TO THE JOINT EXAMINATION BOARD FOR TEACHERS OF THE DEAF, ETC.

### II.[1]—THE CLASSIFICATION OF THE DEAF.

IN my first article I gave some account of the practice in different countries in regard to the classification of the deaf child for purposes of education, and I pointed out that, in two great nations at least, there was ample opportunity for evolving a system that should be as near perfection as it is possible to attain in the light of modern knowledge. These countries are the United States, where a series of experiments is being carried out on a large scale and practically regardless of expense, and England, and especially London, where the evolution of a system of classification may be said to be in an active stage. London, the metropolis of the world, the hub of our great Empire, has the right, if she will but use it, to take the leading part in this great work for humanity, and I am confident that, could her citizens but be brought to take an active interest in the subject, a properly organised system would shortly become an accomplished fact.

Among the beneficial results that must accrue from the working of school medical inspection should most certainly be included a practical and scientific classification of deaf children. This is to be expected because, with the increased interest in and wider knowledge of the physiology of education will come a better recognition of the vast, the paramount importance of perfect hearing to the scholar. The question of the teaching of the deaf will therefore appeal to a larger and more extended mass of educationalists instead of to the somewhat limited body more immediately interested hitherto. Further, the periodical assembling of international congresses on school hygiene must tend, in the near future it is to be hoped, to make any improved scheme of classification an international one, to be more universally adopted and to approach more nearly to perfection because of the more varied experience that can be brought to bear upon it.

The systems of classification at present in practice, and which I have already outlined, are by no means equal in merit. In some countries—as, for instance, in Denmark—the method in use is more liberal in conception, more practical in execution, than in others. In some, again, it is fettered by prejudice or cramped by the too narrow views of those by whom it was framed or with whom rests its application. That is why, in the United States, the achievement of great results is likely, because the system is there in an experimental stage, and there are no very hide-bound customs and prejudices to be overcome before the best arrangement can be evolved.

When it is considered how widely the methods of deaf education and the legislation concerning them vary in different parts of the world, it is not surprising that opinions as to the classification of the deaf child are equally variable, or that a very considerable literature has accumulated thereon. A study of this literature and of the opinions that it represents is alike interesting and disappointing. I have no intention to review these opinions, but I would point out that the subject has been often too much obscured by the bias of the writers, according as they are pure oralists or enamoured of various other methods, combined or otherwise. There can, however, be no doubt that the opposition to pure oralism is diminishing steadily as the latter becomes more and more improved by the experience of its advocates. One feature of the different schemes of classification stands out conspicuously to those whose prospect is not obscured by prejudice—they have been built upon too shallow a foundation, conceived from a too limited point of view. So far as my own knowledge goes, Kerr Love, of all writers upon deaf education, is the only one who has spoken from a broad standpoint and with an eye which commands an extensive horizon. He asserts[2] that "further progress in the education of the deaf-mute depends not on the study of methods of deaf education, but on a study of the deaf themselves, a study which will give a scientific classification, and which will enable existing methods to be applied with greater efficiency," and he has suggested that a better classification of the deaf would be into two groups:—"1. The subjects of 'surdism.' Those congenitally deaf or becoming deaf so early in life that no speech will develop apart from tuition. 2. The semi-deaf and semi-mute. The former have some speech in virtue of their power to distinguish the separate tones of the human voice; the latter may have no hearing at all, but speak in virtue of the hearing and speech present before deafness occurred.[3] It is generally assumed that the semi-deaf belong wholly to those having become deaf adventitiously. Most of them do so, but a few, as we shall see, belong to those *congenitally* deaf."[4] This author, in striving to obtain a rational and practical classification, has followed the only really right direction—viz., the direction of the *individual*, based not upon abstract ideas, but upon actual facts, facts that are staring us in the face, facts that we can glean only *from a study of the deaf child himself*. This is alone sufficient to place Kerr Love in the front rank of modern writers upon deaf education.

But this classification does not go far enough. The term "deaf-mute," as applied to the deaf child requiring special teaching, which is always cropping up in matters of deaf education, has been a great stumbling-block in classification. This has been accentuated by the entirely erroneous tendency among those ignorant of the deaf child to class him with the mentally defective and imbecile—a tendency recently exhibited in a remarkable manner by one who gave evidence before the Divorce Commission, in which the congenitally deaf were classified with lunatics, idiots, imbeciles, feeble-minded, sane and insane epileptics, and chronic inebriates! The education of the deaf is no narrow question which concerns only the deaf-mute, it is a far wider one which embraces, or should embrace, the teaching of all sorts and conditions of children who have, to any extent, however small or however great, lost the sense of hearing. Kerr Love has recognised this and substitutes the term "deaf child" for that of "deaf-mute," and I believe that, at no very distant date, educationalists and, after them, legislators will recognise this fact, and that the future education of the deaf will form a vast system which will comprehend the proper method of teaching the deaf from the very slightly deaf child to the blind and mentally defective deaf-mute. That any scientific classification of the deaf child for educational purposes will have to be thus widely inclusive must be patent to all who have given the matter proper consideration. Once this great fact has become recognised and admitted it will be but a short step to the introduction into every country of one universal and international system of deaf education.

As I pointed out in the concluding paragraphs of my first article, changes which have begun to take place in the education of the deaf show that it is becoming more and more recognised that not only the deaf-mute, or, as I prefer to call him, the very deaf child, requires special education to fit him for useful, self-supporting, and self-respecting citizenship, but also the scholar with a, comparatively speaking, much less degree of deafness. And this, it may be fairly and confidently asserted, is due to the awakening of educationalists, by the establishment of efficient school medical inspection, to a sense of the necessity of a study of the *physiological* aspects of education.

Upon what system, then, must a rational classification of deaf children for purposes of education be based? It should, as I have indicated, be made to include *every child who shows any sign of loss of hearing, be it ever so great or ever so small.*

The form of classification which, so far as my present opinion goes, would be best for adoption is a modification of that foreshadowed in my paper on Deafness in Relation to School Medical Inspection, written in 1908.[5] It is to some extent a modification of those advanced by Laubi[6] and Kerr

[1] Article I. was published in THE LANCET of Feb. 25th, 1911, p. 495.

Love.[7] It necessitates the preliminary inspection of all school children in the first year of school life and a special examination by an experienced otologist of all those who are found wanting in this respect. By this means the deaf may be classified into three primary groups—the very deaf, the semi-deaf, and the slightly deaf. Not only would this inspection lead to a more efficient classification for education, but of the whole number of cases detected by this method some 50 per cent. could be cured, and of the remainder a good proportion would be capable of considerable improvement. It would thus serve a double end—efficient education and efficient treatment, at which all rational school medical inspection must aim, or it is futile.

One word here as regards efficient treatment. It is one thing to talk about it, another thing to obtain it. With the detection of early deafness by school medical inspection should come prompt treatment, but, however much school medical inspection may insist upon this, there are two obstacles at present in the way—the attitude of the parent and the attitude of the practitioner. Both want waking up, both want educating in the matter. The former is too often neglectful of the best interests both of himself and of his child. Life is hard and time is precious, but intact senses are of yet greater value, and the parent must have it brought home to him by argument and, if necessary, by legislation that he is not doing his duty to the child he was instrumental in bringing into the world unless he does the utmost in his power to preserve not only his general health but that of his special senses. It is largely the general practitioner's duty to bring the parent to a proper sense of his obligations, for he is the expert with whom the father or mother comes most in contact; but, as I tried to point out in my paper on the duty of the practitioner to the deaf child,[8] not infrequently the practitioner requires educating also, and in some cases not merely the general practitioner but the specialist as well. Were the general practitioner and the specialist more alive to this fact and the parent more amenable, there would be a far less number of deaf people in the world.

Between the three groups of deaf children obtained by the method suggested above there is no absolute line of demarcation. In the very deaf class must be included the normal and defective (blind and mentally deficient) deaf-mute and those with residual hearing (vowel hearing or for very loud speech close to). The semi-deaf should comprise those who are possessed of a greater degree of residual hearing, sufficient to give them a certain amount of residual or natural speech—the "semi-mute." The slightly deaf may be divided further into two groups of "very slightly deaf" and "hard of hearing." The educational methods necessary for the efficient teaching of the three primary divisions range from the various deaf schools to the ordinary hearing classes of the elementary school. Bezold considered that school work is possible when the scholar can hear loud speech at two metres, as the teacher can generally manage to place himself at that distance from him; those deaf children whose minimal distance is less than half a metre he thought could be taught if the teacher can pay him special attention. With this opinion, however, I cannot wholly agree. In large classes it is impossible for the teacher to pay much individual attention to a child who can only hear loud speech at less than half a metre, and one whose distance for the same vocal effort is two metres must, even when placed in the front desks, lose a large part of the instruction offered. Our aim is to obtain for the deaf child the best education possible, and, even if he is a good lip-reader, a child with the defect just described cannot fulfil this end. The scholar has to receive instruction whilst he is bending over his exercise or reading his book, and he must not lose the thread of an explanation given by the teacher who has his back to him whilst writing on the blackboard or explaining a diagram. Hence the test that must form the basis of classification in the slightly deaf class of child is what is known as the forced whisper. For practical purposes of efficient teaching slightly deaf children should be subdivided by this means into the very slightly deaf who can hear the forced whisper at three feet or over, and the hard of hearing whose acuity is less than that distance. And into this test the mental quickness of the individual scholar must also enter. Indeed, in every classification two factors—degree of hearing and mentality—must be taken into consideration. The very slightly deaf (whisper three feet or more) can very well be taught in an ordinary hearing class, the worst specimens, from either the hearing or mental point of view, being kept in the front row. The hard-of-hearing child (whisper less than three feet) requires more than this; he should receive a part of his curriculum in the front row of a hearing class, whilst he also receives instruction in lip-reading in a special "hard-of-hearing" class where attention can also be paid to his speech and any existing defect of which can there be remedied. He could be returned permanently to his ordinary hearing classes when he is fit to do so in the opinion of his teacher and the medical officer. These hard-of-hearing classes could be held upon specified days of the week and should be in charge of a visiting teacher who is a certificated teacher of the deaf. Such classes ought not to contain more than 15 scholars on the roll at the utmost. Probably, too, there would have to be two classes, one for pupils between the ages of 5 and 10, the other for older children; the experience at the hard-of-hearing experimental class recently instituted by the London County Council seems to indicate this. It is important that these classes should be held in hearing schools in order that the scholars should not be permitted to mix with the very deaf children of the special schools.

The semi-deaf class comprises those who cannot hear the forced whisper and whose hearing for spoken speech is four feet or less,[9] a comparatively considerable amount of residual hearing when contrasted with the deaf-mute. It is obvious that the range of hearing in these cases will be wide and that the factor of individual mentality will be of even greater importance than in the slightly deaf class. Hence these children will naturally fall into two groups—the better cases and the worse cases. The former, scholars of good mentality, fair residual hearing, and natural or residual speech,[10] would be best educated as permanent units in special classes under teachers of the deaf. It is to these classes that the present experimental hard-of-hearing class, already mentioned, is more nearly approached. These classes should also be held away from a deaf centre to prevent the children attending them from mixing with the very deaf either at work or at play. The very deaf and the totally deaf differ markedly in their method of thought from their more fortunate fellows, and the semi-deaf should, therefore, be made to mix with normal companions whenever it is possible. Moreover, the deaf child is ever ready to pick up the bad habit of signing, even when his hearing defect is of a less degree, and such habits are difficult to eradicate. The child possesses the faculty of imitation even more than does the man, and consequently exercises it whenever he gets the chance. It is thus that stuttering may arise, and one signer in an oral class of deaf children will readily find willing imitators.

The worse cases, with more marked degrees of deafness of doubtful mentality, or with defects of speech ("semi, mute"), are on the borderland beween the better cases of the semi-deaf and the very deaf. They would probably be taught more advantageously in special classes in a deaf school under the oral system, *the study of each individual child being of paramount importance.* Here comes in the great question of day schools *versus* residential schools, a question upon which opinions have been much divided. In this matter, as in most others, the extremist is wrong; what is required is to take a middle course. Where there is no deaf day school near at hand, as in the country districts, it is better for the deaf child to go to a resident institution than not go to school at all. Resident institutions have their uses, and for those deaf children who are defective they are no doubt excellent. But whenever it is possible for a normal deaf child to remain with his parents (provided they are worthy to have him in their care) that is the best environment for him to be in. When this is not possible he should be boarded out with a good foster-mother. Residence in an institution means less opportunity for the deaf child to mix

[7] Transactions of the Second International Congress on School Hygiene, London, 1907, vol. ii., p. 828.

[8] THE LANCET, Sept. 10th, 1910, p. 781.

[9] I must here remark that the distances proposed in this article must not be taken as final; further experience, and especially that gained by the working of this or an analogous system, will be certain to modify them.

[10] This natural or residual speech would, without special training, deteriorate.

with the hearing environment, which is so important a factor in the success of the oral system. Another point in this question is, again, the necessity for studying the deaf child as an individual; the defective deaf are certainly more fit for residential institutions.[11]

With the worse cases of the semi-deaf, like those of the totally deaf, no modification of ordinary hearing school methods is of the slightest use: they must be educated in a special day school or residential institution. Under present conditions the worse cases of the semi-deaf must be taught, as, indeed, they are, with the totally deaf. It is quite likely that it may be found possible later to classify both classes and rearrange the educational methods applied to them to better advantage. If the totally deaf and the worse cases of the semi-deaf fail under the oral method they must not be allowed to influence the oral successes, but must be transferred to a school where the manual or combined systems are taught. Every oral failure is a source of danger to the oral successes, and the sooner this is recognised in deaf schools the better. The oral failure uses signs, and for this reason contaminates the oral success. This matter I have already touched upon in my first article. That is why I am strongly opposed to the institution of a "duffers" class in a normal deaf school. If it is proved that a child, after thorough and careful trial, will never attain to speech, he should be transferred as soon as the fact is recognised beyond a reasonable doubt to a school where systems other than oral are practised. The late Mr. van Praagh, whose experience was very great, once stated that every deaf child, provided that he was not mentally defective or imbecile, could be taught by the oral system, and no doubt this is true provided all obstacles to success are eliminated. It is with a view to the recognition and elimination of these obstacles that the system of classification, which may at first sight appear somewhat elaborate, here suggested has been framed.

A careful study of the mental capacities of the totally deaf and of the worse cases of the semi-deaf is highly important, and those whose defects are pronounced cannot, I think, be properly taught in a day school. In dealing with borderland cases one has to take into account the mental attainments of every child and endeavour to classify him for educational purposes, so that his teacher may get the best out of him. This is by no means an easy thing to do, and it would probably be made easier if the child were got to school at an earlier age. The slightly dull child who may be left hopelessly behind in a class of deaf scholars of normal mentality may appear quite bright in one of the mentally defective deaf because he is *unioculus inter cæcos*, and he is not receiving his full educational rights if he is placed in either class. The mentally defective deaf should be placed in a residential institution, to be got at by methods adapted to each individual case by teachers of proved experience. This is one of the real uses of a resident institution. At the same institution the dull or backward child, the one just referred to as on the borderland, might attend special classes as a day scholar. There are some such children who would so benefit by such a class that they might later be saved to the oral method and be allowed to return to the normal deaf school.

Normal semi-deaf or totally deaf children are better in day schools provided their parents feel their responsibilities sufficiently to help in their education at home, and this home education, in the hands of good parents who loyally help the teacher and the doctor, is of very great value. Where the parents are neglectful and unmindful of their duties, or alcoholic, or responsible for bad school attendance, and where the home surroundings are morally bad, then the child should, for his own sake and for the sake of his future as a citizen (for the State should come, without compromise, before the parent in such cases), be taken from the parents and either placed in a residential institution or, preferably, boarded out with a good foster-mother. I do not write thus without good reason. I have met with cases in which the scholar's whole future, educationally and morally, was being blighted by the unwholesome effects of bad home surroundings and alcoholic or immoral parents. I have seen children making good progress taken away hopping or fruit-picking, or used for purposes of begging, and returned at long intervals to school with all the knowledge they had so laboriously acquired forgotten and wiped out. I have seen children kept from school because the only clothes they had to wear had been taken away and pawned by the parent for drink. The difficulties which lie in the way of the educational authorities in such cases are great, and will remain so as long as the great fetich of the "liberty of the subject" is worshipped, forgetful that liberty really means, as Burke once put it, "equal restraint for all." The machinery that should correct such abuses moves so slowly, and there are so many loopholes for the wrong-doers, that much valuable time is lost before such cases can be remedied, but a very great deal could be achieved if the Children Act were adequately amended and adequately administered.

At the outset of the deaf child's education the parents should be interviewed, and an endeavour made to impress upon them the necessity for regular school attendance and home educational help; they should be enjoined to coöperate with the child's teachers in giving the oral system every possible chance, and should be warned against allowing home influences to degenerate into the substitution of signs for lip language. Here I may point out that good school attendance means, *for the deaf*, as constant and regular attendance as possible. This is of far greater importance for the deaf than for the hearing child. A loss of one schoolday a week means far more for the former than it does for the latter, for the deaf child under present conditions seems to forget what he has learned more quickly than does the hearing child, probably because his command of language, for want of continuous education through the ear, is much more limited.

The defective deaf (blind and mentally deficient) require very special instruction under highly experienced teachers, such as they obtain in our London County Council Centre at Homerton. The blind need to be taught the Braille method as well as special manual systems of communication, whilst the methods upon which the mentally deficient require to be trained are such as those so well outlined by Mr. F. G. Barnes in his paper read before the Third International Congress on School Hygiene, held in Paris in 1910. A school or institution for the defective deaf must be kept for such cases alone it should not have its classes taken up by the imbecile deaf; such cases contaminate the scholars who are capable of education and take up too great a share of the teacher's time, to no purpose whatsoever.

The system of classification here advocated, and which endeavours to give to the individual child the highest form of education to which he is entitled, may be tabulated as follows:—

| Class of deafness. | | Educational treatment. |
|---|---|---|
| A. Slightly deaf... | Very slightly deaf ... | Hearing school, preferably front row. |
| | Hard of hearing... ... | Hearing school and special classes under visiting teachers of the deaf. |
| B. Semi-deaf ... | Better cases... ... ... | Special classes under teachers of the deaf in hearing school. |
| | Worse cases... ... ... | Special classes in deaf day school. |
| C. Very deaf (deaf-mute) ... | Oral successes ... ... | Special deaf day school or residential school (better boarded out). |
| | Oral failures ... ... | Separate classes of manual or combined system in residential school. |
| Defective deaf ... ... ... ... ... ... ... | | Special individual systems in residential schools. |

In a recent paper written for the Third International Congress on School Hygiene [12] I advocated the commencement of the education of the very deaf at a much earlier age than is at present the case in most countries. My reasons for doing so will be given in detail in the third of these articles, and I am strongly of the opinion that the period of instruction should be made to embrace the life of the very deaf child from 3 to 18 years. I mention this here because I consider that this extended period is a natural and necessary corollary to any system of classification of the deaf for educational purposes. There are very strong physiological reasons why the earlier age is advantageous, and these will be stated later. There are equally strong reasons why

[11] It would be better if they were kept in them permanently.

[12] At What Age should the Education of the Deaf Child Commence? British Journal of Children's Diseases, October, 1910.

control should be maintained until a later age than is at present considered necessary by legislators. To give only two of these: it must be insisted that the deaf child is entitled, and justly, to as much advanced education and to as advanced teachers as possible. We have not yet arrived at the time when every precaution is taken to diminish, by negative and positive eugenics, the number of the congenitally deaf, nor have we reached perfection in the prevention of acquired deafness in children. When so ideal a state of affairs has been accomplished we shall not have so many deaf to educate, but until then we have this great problem of the deaf child to face, and it must be faced squarely and the very best done for them that can be devised—for their sake, for the sake of the State, and for the sake of humanity.

Secondly, under the shorter period, the scholar is removed from the teacher's influence just at the time when that influence is most felt, most required, and most likely to make a lasting impression. The first two years of instruction, from three to five years, should be passed in a preparatory class, where the child's capacity, his mentality, and his chance as an oral success or failure could be ascertained by experienced teachers. Teachers of the highest experience and capacity are most needed for this part of his training. Much precious time could be saved by this arrangement, and each child could be drafted at the age of five years into an elementary deaf school in a better state of fitness for his curriculum.

It will be remembered that in the first of these articles I postulated certain conditions that I considered to be needful for the ultimate improvement of deaf education. The first of these is that discussed in the present paper, the third and fourth may be reasonably noticed now. The need of greater care of the deaf child whilst at school, by care committees and similar means, whereby it can be assured that his attendance at school is regular, his meals are adequate, that he is not neglected or exploited by his parents, and that he is removed from the influence of bad companions and bad home surroundings, is a consideration which hardly requires discussion. Parts of it have already been touched upon, and all I need add is that legislation is urgently needed to ensure greater control over the deaf child, and more people are wanted to take an interest in him. There seems a curious ack of sympathy with the deaf, especially when it is compared with the quantity lavished upon that much happier class of the physically defective—the blind. It seems so difficult to make people understand the position of the deaf child, that he is neither imbecile nor mentally deficient, but simply a normal child deprived of that sense which might be, of all his senses, of the greatest educational value to him. It does not take long to discover from contact with deaf children what a charming and loveable class they are, and I would appeal to the charitable to take up their cause with more vigour than has yet been the case.

The fourth need postulated was the encouragement of the deaf child to mix with hearing people. This would be greatly helped by an extension of the later educational course. The last two or three years, from 15 or 16 to 18, would be occupied in an advanced school where special training would be given in some trade or occupation and where moral training suitable to the more advanced age of the pupil would be made a feature. Possibly it might even be better if the advanced school life should be, as at present, from 14 to 16, scholars from 16 to 18 passing to a college for the deaf, where they could obtain a course of training which should be a modification of the ordinary university life.[13] This could, however, be settled when the extension of the educational age had been secured by legislation. This system, or a modification of this system, is already in vogue in some parts of the United States, where it appears to have been eminently successful.

I feel sure that by some such arrangement as is here advocated the very deaf child would leave his educational courses better equipped intellectually, usefully, and morally than can possibly be the case under present methods. The aim of all education is to fit the child, in the best possible manner, for self-reliant, self-supporting citizenship, and if this is so for the scholar who is fully equipped as regards his senses, it holds good equally for the normal deaf child. I believe that the whole secret of deaf education is to give to the young deaf child that physiological training that his defect has denied to him and whereby he is, at seven years, like a normal child of two in mentality, and to keep him longer at school in order to give him as advanced an education as is possible to equip him for his career in the world in order to remove, or at least to obviate, the handicap which nature has imposed upon him.

In conclusion, I wish to touch upon a matter which is of a very delicate nature, alluded to in the concluding words of the fourth postulate in the first article, "a more careful supervision of religious missions to the deaf." Nothing is farther from my mind than to make any charge of neglect, or to write anything that can reflect in the least degree upon or wound the feelings of any person or persons connected with any particular mission, all of which are conducted by high-minded, disinterested, and, in many cases, self-sacrificing men, actuated solely by the unselfish wish of benefiting the deaf community and ameliorating the conditions under which they live. But these worthy people are too apt to lose sight of other and important considerations in their ardour for their religion. The question is a delicate one and requires careful and tactful handling. The free signing which goes on amongst the deaf-mutes who attend these missions cannot be controlled and those in authority are powerless to prevent it. If any teachers of the deaf read these articles they will fully understand to what I allude, and may, possibly, be prevailed upon to give their own experiences of this matter. The remedy lies, of course, in the better education of the deaf, and the universal encouragement of the oral system among the deaf and the discouragement by missioners of its abandonment after leaving school. Until then, however, I would earnestly advocate that it should be the future care of these missions to regulate their meetings with a view to greater restraint. They should hold different sittings for different sexes (especially when lantern lectures are given), and, an item of equal importance, they should hold different meetings for the old and for the young.

*(To be concluded.)*

[13] If education commenced at three, instead of at seven, a further modification of what is here advocated would be possible, for, as will be seen in the third article, the effect upon speech and language teaching would be such that the scholars would be much more advanced than they are at the present time. There are, moreover, reasons for believing that a university course in an ordinary hearing college would be more acceptable and more advantageous than the foundation of a deaf university. The Gallaudet University in the United States is a great success, but the alternative would be better calculated to encourage the mixing of the deaf and the hearing.

## A CASE OF SUPRARENAL APOPLEXY.

BY RUPERT WATERHOUSE, M.D. LOND., M.R.C.P. LOND.,
PATHOLOGIST AND ASSISTANT PHYSICIAN, ROYAL UNITED HOSPITAL, BATH.

FOR the clinical details of the following case I am indebted to the house physician, Dr. Norman W. Steinberg.

A male child, aged 8 months, was admitted into the Royal United Hospital under the care of Dr. E. J. Cave on Oct. 30th, 1910, with the history, obtained from the parents, that throughout the morning the child had been very drowsy and had "looked strange," but that he had not seemed to be in pain, had taken nourishment readily, and that the bowels had acted as usual. About 3 o'clock in the afternoon he vomited, and as the baby appeared to be getting worse he was brought to the hospital. Previously the child had always seemed perfectly healthy. He had been breast-fed until three weeks before admission, when a mixture of cow's milk and water was substituted. On account of the parents' conscientious objection the child had never been vaccinated. The mother had had one other child, who died at the age of two years from pneumonia after an illness lasting ten days, and two miscarriages.

On admission the infant was obviously very ill: complexion grey, eyes dull, breathing rapid, shallow, and noiseless; temperature 100·4° F., pulse 140, and respirations 72. Râles could be heard all over the chest, especially at the bases behind. The abdomen was soft and not tender. There were no signs of meningitis, and nothing abnormal was to be seen in the mouth or fauces. Two hours after admission an extensive eruption of purple spots and blotches appeared over the whole trunk, upper arms, and thighs. The temperature had fallen to 99·4°. The child rapidly grew worse,

the face becoming cyanosed, and death occurred at 7.30 P.M., four hours after admission. There were no convulsions throughout.

*Necropsy.*—The post-mortem examination was made 22 hours later. The body was that of a well-formed, well-nourished infant. It bore no vaccination marks. On the trunk, front and back, and on the limbs down to the elbows and knees, was visible the blotchy purpuric eruption mentioned. The larger patches were dull red rather than purple, and appeared to be somewhat raised. A few small spots were to be observed on the neck and on the face in front of the ears.

The lungs were congested and œdematous. The heart appeared healthy except that on the auricular surface of the mitral and tricuspid valves, close to the free margin, were a few very tiny beady elevations. There were no subpleural or subepicardial petechiæ. The liver was pale; the spleen and kidneys normal. The intestines were pale and collapsed; the mesenteric glands not enlarged. The suprarenal capsules were striking objects, even before their removal from the body; of little more than normal size for a child of this age, they were both of a deep purple colour and evidently the seat of hæmorrhage. The extravasation of blood had taken place into both the cortical and medullary portions, but no bleeding had occurred into the adjacent tissues. Microscopically the structure of the medulla was seen to be completely destroyed and replaced by effused blood. The arrangement of the columns of cells in the cortex could be made out, but the cells themselves had largely disappeared, their nuclei alone remaining, whilst everywhere were to be seen large numbers of red blood corpuscles. All the other organs appeared natural. The spinal cord was not examined.

Cultures taken from the adrenals, from the spleen, and from the cerebro-spinal fluid all proved sterile. No micro-organisms could be detected in films made from the cerebro-spinal fluid and from the interior of the suprarenal capsules. Sections of the suprarenal capsules were stained by Levaditi's method for spirochætæ with a negative result.

*Remarks.*—Whilst it is not very uncommon to meet with hæmorrhage into the adrenals of stillborn children or of infants dying shortly after birth, and whilst bleeding into these bodies may, rarely, take place in conditions of great venous congestion, it is, with these exceptions, an occurrence which, to judge from the number recorded, is one of considerable rarity.

The case related above appears to form one of a distinct group, examples of which have been described by Voelcker,[1] Still,[2] Garrod and Drysdale,[3] Batten,[4] Andrewes,[5] Talbot,[6] Blaker and Bailey,[7] Graham Little,[8] Langmead,[9] and Dudgeon.[10] Omitting the case of Still, in which miliary tuberculosis also was found at the necropsy, and that of Batten, in which hæmorrhage occurred into one suprarenal capsule only in a boy, aged 2½ years, there remain, including that just described, 15 cases, all infants between the ages of 2 and 15 months, and all of whom died after an illness lasting in the majority less than 24, and in none more than about 48 hours. In all but three a hæmorrhagic rash of greater or less extent was present. Vomiting occurred in 6, diarrhœa in 1, convulsions in 5, and symptoms suggestive of abdominal pain in 3. In several cases signs of bronchitis were present. The temperature—in most between 100° and 103°—in Voelcker's case was 105°, and in one of Graham Little's reached 108° before death. Apart from the lesions of the adrenals and the hæmorrhagic rash, the most constant post-mortem findings have been intense engorgement of the lungs. Blaker and Bailey lay emphasis on hyperæmic swelling of Peyer's patches and of the mesenteric glands, resembling that found in the early stages of enteric fever. Cultures from various organs have in most cases proved negative, but in one of Talbot's a streptococcus was obtained by Drysdale from the suprarenal capsule after death.

The suggestion was made, both by Voelcker and by Andrewes, that theirs were cases of rapidly fatal hæmorrhagic small-pox, and the fact that of these 15 cases only one had been vaccinated, whilst 11 were unvaccinated (the history of the other three in this respect being imperfect), seems to suggest either that there is some relationship between this disease and variola, or that the extent to which vaccination is performed in the country which gave it origin is lamentably insufficient. Since none of these cases seem to have occurred during, or to have been followed by, an epidemic of small-pox, the latter appears the more likely.

# CRANIAL ASYMMETRY DUE TO POSTURAL CAUSES.

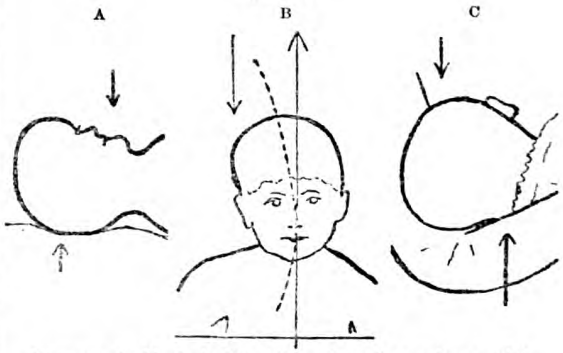
BY HUBERT ARMSTRONG, M.D. VICT. & LIVERP.,
HONORARY ASSISTANT PHYSICIAN, LIVERPOOL INFIRMARY FOR CHILDREN.

FEW, if any, of us attain to the perfection of bi-lateral symmetry; consequently, in common with the rest of the frame, the two halves of the calvarium are rarely exactly alike—a fact which is of importance only on the occasion of a visit to one's hatter.

The causes of *abnormal* distortion may have been forces acting upon the bones from within or from without, and the earlier in life that they have been brought to bear the greater is their effect, owing to the yielding nature of the young bones. In infancy, too, the attention is drawn most forcibly to cranial asymmetries, for any irregularity in the roof is naturally more obvious when the thatch is thin. Many interesting abnormalities have pre-natal origin, or are due to traumatism in parturition; others arise from cranial or intra-cranial disease. In this short note, however, I am only dealing with posture as a cause of deformity, and more particularly with one characteristic variety.

The effect of posture is, of course, the application of the law of gravitation. Now the position of the normal baby is so frequently varied that gravitation, if it have *any* effect in moulding the cranium, acts symmetrically in the production of a normal skull. When the baby, or the circumstances surrounding it, are not normal, the action of gravity produces variations. A rachitic child, for instance, being soft of bone and inactive muscularly, lies much on its back, and the calvarium is consequently pushed forwards—or rather "upwards," as the child lies. This is one of the factors concerned in the production of the well-known frontal prominence of the rickety head. To be strictly accurate, it is the face and base of the skull which, acted on by gravity, are pulled downwards (backwards) away from the calvarium, which, supported by the occiput, lies on the pillow and can descend no further (Fig. 1 A).

FIG. 1.



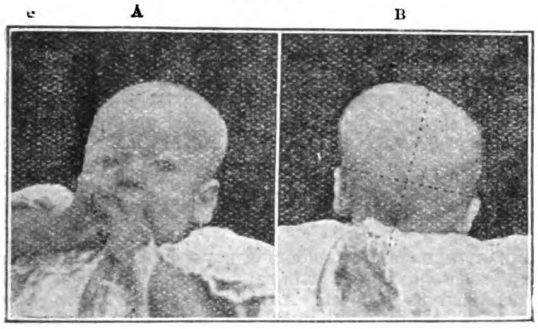
Diagrams to illustrate the action of gravity causing cranial asymmetry in A, rickets, B, torticollis, C, an infant nursed at one breast only.

In cases of so-called congenital torticollis, which are probably due to injuries of the sterno-mastoid and adjacent muscles at birth, a marked facial and cranial asymmetry is seen. The face is said not to develop fully on account of pressure on the carotid artery. This may be so; but if a sheet of paper be held in front of the face dividing it vertically into two halves, it will be seen that not only is the affected side smaller, but there is also a projection of the skull-cap and chin towards the same side; a central line drawn down the face will thus be curved with the convexity

away from the contracted muscles (Fig. 1 B, the outline of which is traced from a professional portrait). This, I think, may also be the effect of gravity, acting partly as in the first instance (the child lies more comfortably on the healthy side), in part directly, when the infant is held in the sitting position, and sometimes as will be mentioned shortly.

But by far the most marked examples of cranial obliquity occur as the result of nursing the infant at one breast only. The lop-sided head which ensues is not so generally known as I should have expected. Two patients shown recently at the Liverpool Medical Institution exemplified the deformity well. Both are boys—one aged 5 months, the other 7 months. In one case the mother's left nipple is so depressed that suckling with that breast is impossible; in the other the right breast has never secreted milk. The heads of the two children exhibit a similar deviation (Fig. 2 A); in the case of

FIG. 2.



Reproduction of photographs of infant nursed at right breast only.

the infant nursed at the right breast to the left, in the other to the right. In these cases it is the weight of the brain which pulls the head out of shape (Fig. 1 C). As this weight lies chiefly posteriorly, and also as the arch of the calvarium has firmer support in the frontal region, the greater deformity is at the back of the head, and it is best seen in that aspect (Fig. 2 B).

The commonest reason for suckling an infant at one breast only is an abscess in the other, and one may often astonish an unobservant mother by diagnosing that affection from the appearance of her baby's head. But one must not be too sure. In one case in which I was consulted there had been nothing wrong with the breast, but the child having a slight degree of torticollis found a difficulty in getting his head round to the corresponding breast; so the fault was in the child and not the mother. Consequently, whether the alteration in the position of the head engendered by "congenital" torticollis can of itself give rise to a postural asymmetry or not, it certainly may do so secondarily in the manner described.

In the patient whose photographs are reproduced there is a sort of vicious circle temporarily established at present. The child is beginning to sit up unsupported; the additional weight in the left half of the head causes it to drop over to that side, thus perpetuating the state of affairs which led to this extra weight. With increasing strength this droop will be overcome. It is not shown in the photographs, in which the head is invisibly supported.

I imagine most of these heads straighten themselves when suckling is over. One of the mothers brought me a daughter, aged 6 years, whose head was similarly affected in infancy, and, so far as an examination through the shock of hair she possesses can determine, there is no evidence of the condition left now.

For treatment I think it is well to instruct the mother or nurse to counterbalance the too frequent posture of nursing on one arm by carrying the child an equal length of time per diem on the other. As the baby generally sleeps after being fed, this involves trouble, and the direction is rarely followed out. In addition, the mother should be told to be particularly careful while nursing to support that part of the head which sags, rather than to make the carrying point the usual one of the neck and base of the skull. But I have seldom seen much improvement until weaning has taken place.

Liverpool.

# A CASE OF RODENT ULCER OF THE THIGH.

BY HERBERT E. FRIEND, M.R.C.S. ENG., L.R.C.P. LOND.,
AND
T. CRISP ENGLISH, M.B., B.S. LOND., F.R.C.S. ENG.

RODENT ulcer rarely affects any part other than the face and scalp. Mr. A. A. Bowlby recorded a series of 66 cases of rodent ulcer, all of which affected the face and scalp, except two which occurred on the nape of the neck and on the back respectively. The following instance in which a rodent ulcer occurred on the skin of the thigh is therefore of great rarity, if not unique.

The patient was a widow aged 68 years. She first noticed a nodule on the outer aspect of the thigh at the junction of its upper and middle thirds in 1874; this nodule was painless and caused no discomfort, but from time to time it broke through the surface and then healed again. It remained in this condition until 1896, when the patient sustained a fracture of the right femur below the surgical neck; the splint, though well padded, caused irritation of the nodule, and a sore of about the size of a pea resulted. During the following years the sore slowly increased in size, and when seen in 1905 was of about the size of a sixpenny-piece. Removal was advised, but the patient would not consent to this. In 1907 the ulcer was again seen, and removal was again advised; the patient was still unwilling to have this done, and as the surface of the ulcer was unhealthy it was cleaned with applications of peroxide of hydrogen; now for the first time the edges appeared raised and thickened.

In September, 1909, examination of the ulcer showed that it had increased to the size of a crown-piece; it was somewhat irregular in outline and moderately painful, its edges were rolled over and indurated, and there was an island of cicatricial tissue near its centre; there was no enlargement of the lymphatic glands. The patient was willing to have the application of X rays, and these were used once by Mr. Cecil Lyster; but when it was pointed out to her that the use of this treatment would have to be extended over a long period, and that the growth was now in an active state, she at last consented to its being excised. This operation was performed on Oct. 8th, the anæsthetic being administered by Dr. F. W. Cock. The growth was freely removed by elliptical incisions which were carried down through the deep fascia. The wound healed well. The ulcer and the surrounding tissues were examined microscopically by Dr. R. Salusbury Trevor, pathologist to St. George's Hospital, who reported that the appearances were typical of rodent ulcer.

The scar remained sound until October of last year, when the patient noticed a little thickening near its lower end. This thickening slowly increased, and when seen by us in November was a small flat-topped nodule lying just beyond the lower end of the scar, obviously a "recurrence" of the growth. This nodule and a large area of the surrounding skin were excised on Nov. 25th.

The following authorities have recorded cases of rodent ulcer which have been observed in places other than the face and scalp: H. Betham Robinson reported one occurring over the male breast [1]; A. A. Bowlby, an enormous ulcer on the back in addition to five on the face and one on the nape of the neck [2]; J. Hutchinson, jun., a case in which there was one on the forearm and one in the groin [3]; T. S. Pigg, a case in which there was one in each groin [4]; H. D. Rolleston, an ulcer near the umbilicus [5]; Radcliffe Crocker mentioned one just above the sacrum and one in the groin [6]; and Colcott Fox describes an ulcer over the sternum.

Examples of rodent ulcer on the trunk are not very uncommon. Mr. G. Lenthal Cheatle, in a paper on the Incidence of Cancer,[7] records 17 cases which he had been able to collect. These cases are illustrated by reproductions of the original photographs and drawings, and the ulcers occurred in the following positions: back of shoulder

[1] Transactions of the Pathological Society, vol. xliv., p. 147.
[2] Ibid., vol. xlv., p. 159.
[3] Ibid., vol. xlviii., p. 224.
[4] Ibid., vol. xl., p. 300.
[5] Ibid.
[6] Diseases of the Skin.
[7] Brit. Med. Jour., April 29th, 1905.

(J. H. Sequeira); back of shoulder (Sir J. Hutchinson); back near mid-line (A. Reid); scapular region (Sir J. Hutchinson); scapular region (A. Reid); lumbar region (Sir Victor Horsley); abdominal wall (Sir Victor Horsley); over spine (W. A. Pusey); coccygeal region (Norman Walker); sternal region (Dr. Mill); axilla (McAdam Eccles); anterior scapular region (Sir J. Hutchinson); mammary region (Dr. Jacobs); front of chest (J. H. Sequeira); abdomen (Sir J. Hutchinson); and groin (Royal College of Surgeons of England Museum).

Mr. Cheatle tells us that since the publication of this paper he has come across four other instances of rodent ulcers occurring on the back in the areas supplied by the internal divisions of the posterior branches of the dorsal nerves.

The list of cases which has been given could be added to considerably, but it will serve to indicate the distribution of those ulcers which do not occur in the usual situations.

## NOTES ON A CASE OF RETENTION OF URINE.

BY GEORGE W. BURY, M.B., CH.B. VICT.,
RESIDENT SURGICAL OFFICER, NORTH STAFFORDSHIRE INFIRMARY.

I REPORT the following case on account of (1) the extremely large quantity of urine retained in the bladder without rupture; and (2) the rapid recovery of vesical tonus after such an enormous distension.

The patient, a married woman, aged 37, was admitted to hospital with the following history. She had apparently been quite well until 14 days previous to admission, when she complained of severe dragging pains in the lower part of the abdomen, accompanied by nausea and vomiting. She noticed also that she had some difficulty of micturition, but passed a normal quantity of urine. She recovered in 24 hours and was able to do housework. Eleven days later the pain recurred and was very severe, and she had great difficulty in passing urine, and then only a very small quantity. She also noticed that the abdomen was getting larger and on this account called in a medical man, who ordered her to hospital.

Upon admission to hospital the patient was in a comatose condition; pupils contracted, equal, and reacted to light. She moved slightly on being spoken to loudly, but did not understand, and was very irritable on being moved. Breath very offensive; skin cold and clammy; pulse feeble and thready, rate 138; temperature subnormal; respirations shallow and sighing.

Upon inspection of the abdomen a large tumour was seen completely filling the hypogastric and umbilical areas, being rather more prominent on the right side. The limits of the tumour were well defined and it was arising from the pelvis. On palpation the tumour was quite hard. The upper level lay midway between the umbilicus and sternum, 1½ inches to the right of the middle line; the tumour was slightly moveable, but no fluid thrill obtained. The tumour was dull to percussion; the flanks of the abdomen and the side of the pelvis were quite resonant. Vaginal examination revealed a lax vagina from old ruptured perineum not repaired. The arch of the pelvis was distinctly felt, no bladder seeming to intervene. Just within the reach of the finger was a mass pressing anteriorly which felt like a soft cervix, but difficult to make out with certainty. The vaginal vault was capacious, and occupying the pouch of Douglas was a hard mass with definite limits and probably connected with the uterus. Per rectum, about two inches from the sphincter, there was a large tumour, palpable, hard but resilient, slightly moveable, which lay in the hollow of the sacrum. It was possible to feel the sacral promontory above the tumour, and the tumour was completely incarcerated in the pelvis, and was probably a retroflexed gravid uterus. This tumour was quite distinct from the abdominal tumour.

A catheter was passed with difficulty, the urethra being lengthened. A stream of urine began to flow under very high pressure. This was quite clear and not offensive; 166 ounces were withdrawn. Urine was of specific gravity 1030, acid; no albumin, sugar, or pus. On examining the abdomen the original tumour had quite disappeared. An attempt was made to reduce the pelvic tumour, but this was impossible. An anæsthetic was administered, and with two fingers in the rectum the uterus was replaced above the promontory, and now lay at the level of the umbilicus. A Smith-Hodge pessary was inserted.

The uræmia was now treated by saline infusion, injection of digitalin, calomel, and warmth applied to the skin. A catheter was passed four-hourly, and at first passage 56 ounces of urine were withdrawn. The general condition gradually improved; bowels acted, patient perspired freely, and consciousness returned, though some delirium was present. Forty-eight hours after admission she passed urine normally and became quite conscious. On examination of the abdomen a pregnant uterus was palpable at the level of the umbilicus; nothing else abnormal. Seven days after admission the patient was out of bed, feeling quite well and wearing the Hodge pessary, which kept the uterus in normal position. She had no trouble or difficulty with micturition and the urine was normal in quantity and in every other way. She was discharged quite cured 14 days after admission and advised to wear the pessary for at least two months.

I beg to thank Dr. G. H. Hatton for supervising the notes of this case and allowing me to publish the same.

Stoke-on-Trent.

## INFANTILE DIARRHŒA.[1]

BY WILLIAM TIBBLES, M.D. CHICAGO (HON. CAUS.), L.R.C.P. EDIN., M.R.C.S. ENG., &C.

BREAST-FED children seldom or never suffer from diarrhœa. It is a consequence of artificial feeding. The causes may be classified as follows: Autogenetic: (1) gastro-enteric catarrh, (*a*) acute, (*b*) chronic; (2) intestinal fermentation; (3) toxæmia. Heterogenetic: (4) mechanical irritation; (5) nervous influences; (6) drugs; (7) improper feeding; (8) bacterial infection.

*Catarrhal diarrhœa* is the ordinary looseness of the bowels which affects many infants in early life, especially during dentition.

*Mechanical irritation* is the cause of diarrhœa resulting from attempts to feed children with bread, barley flour, oatmeal, and proprietary foods containing much starch. In older children diarrhœa often follows the consumption of partly cooked cereals, fruit containing seeds (strawberries, currants, gooseberries), dried fruit (currant cake, seed-cake, &c.), green vegetables (boiled cabbage, cauliflower, celery, lettuce, watercress), all of which act virtually as foreign bodies, irritate the mucous membrane, cause increased peristalsis, and sometimes a catarrhal inflammation of the mucosa.

*Nervous influences* are a frequent cause of diarrhœa—e.g., when the surface of the body is chilled, or when the ganglionic system is disturbed by excessive heat, fatigue, exhaustion, fear, or excitement. In very young children coldness of the feet is a very common cause of stomach-ache and looseness of the bowels. Many instances of diarrhœa are characterised by an exaggerated peristalsis. In such cases taking a meal, a chill, fright, or excitement will immediately start a violent peristaltic action, in consequence of which the food is hurried along the alimentary canal and undigested food appears in the fæces. This is often called lienteric diarrhœa.

The effect of drugs needs scarcely be mentioned, except to remind you that many drugs are excreted by the mammary gland. An aperient will affect the child through the mother's milk. In the same way cabbage, cauliflower, pickles, stewed prunes, and other fruits consumed by the mother will affect the nursing child.

*Diarrhœa due to the food of the infant.*—(*a*) It may arise from an excess of casein or an inability to digest it; the curd acts as a foreign body and sets up diarrhœa by mechanical irritation, or it undergoes putrefactive decomposition and gives rise to a toxæmia of which the diarrhœa is a symptom.

(*b*) It may arise from an excess of carbohydrates, especially maltose from the malted foods of commerce.

(*c*) It may arise from an excess of fat, especially the fat of cow's milk. The scientific basis of the requirement for plenty of fat in the child's food is beyond dispute. But it

[1] A paper read before the Nottingham Medico-Chirurgical Society on Nov. 15th, 1910.

must be digestible fat, such as that of human milk, fresh cow's milk, or gravity cream. The food of infants from birth to 6 months should contain 4 per cent.; from 6 to 9 months, 4·5 per cent.; from 9 to 12 months, 4·0 per cent.; and from 12 months onwards, 3·5 per cent. of fat. It is evident that diluted cow's milk does not contain the required proportion, and naturally we recommend the addition of cream. This additional fat has the effect of preventing the aggregation of casein into large masses of curd, and rendering the milk more easily digested. It has the further effect of increasing the weight of the child, improving the nervous system and the condition of the blood-making cells in the marrow of the bones. But occasionally infants cannot digest food containing more than 1 per cent. of fat from cow's milk; it gives rise to indigestion, fat diarrhœa, acidosis, and convulsions. The normal fæces of the breast-fed child may contain some fat. But the fat of cow's milk, consisting of much larger globules, is less easily digested than that of human milk, is not so readily saponified and absorbed.

The difference in the size of the fat globules of human milk, milk fresh from the cow, and in gravity cream is very great. But the difference between the fat globules in human milk and in separator cream is far greater. The act of centrifugalising the milk, in order to separate the cream sold in shops, breaks up many of the milk globules; they become aggregated together and form tiny particles of butter. The emulsion is more or less destroyed. Many children cannot digest such cream, vitality languishes in consequence of the deficient absorption, the oxidative processes in the body fail, and the undigested fat causes diarrhœa. The disturbance of the digestive processes leads to the formation of oxybutyric acid and acidosis. As a further result there is an increased destruction of protein in the organism to supply energy, while the imperfect nitrogenous metabolism leads to the excretion of ammonia.

*Diarrhœa due to infective causes.*—This form of diarrhœa is most prevalent in the summer time, and hence is called "summer diarrhœa." The predisposing causes are the age of the child, its constitution, bad feeding, and bad environment. Given one or more of these predisposing causes, a slight exciting cause will start the diarrhœa. The lesions in the intestines are slight and bear no relation to the severity of the illness. The chief symptoms are due to the absorption of toxins in the food or produced in the alimentary canal by bacterial decomposition. One of the most striking features is the prevalence of the disease in hot weather. An epidemic does not begin until the mean temperature of the atmosphere is 60° or 61° F., and remains so for several days (four to eight days). Neither the humidity of the atmosphere nor the rainfall appears to have much influence upon the progress of the epidemic or the mortality. The epidemic begins towards the end of July, is in full force throughout August, and lasts well into the third week of September. The mortality is highest during the first weeks of the epidemic because very few delicate infants are able to withstand the first month of great heat.

But heat alone is not sufficient to give rise to an epidemic. It is of infectious origin. The temperature which is necessary for the production of diarrhœa is the same as that most suitable for the activity of bacteria. The disease is most common amongst recently weaned children or those fed wholly or partly on cow's milk. Cow's milk ordinarily contains an enormous number of bacteria, and is an admirable medium for the culture of various pathogenic bacteria. The infection which causes diarrhœa may be of two kinds.

(*a*) *Autogenetic*, resulting from the normal bacterial flora of the intestines becoming pathogenic, the change in the action of the bacteria and the nature of the products being dependent upon the altered conditions in the alimentary canal. We have as a result a severe gastro-enteric intoxication which is not always distinguishable by its clinical signs from acute indigestion. As a rule, however, the temperature is higher, the nervous prostration is greater, the stools more liquid and offensive; and the disease is epidemic.

(*b*) The *heterogenetic* form of diarrhœa is far more fatal. It is due to the introduction of bacteria with the food, usually milk. The bacilli are streptococci, staphylococci, colon bacilli, the proteus, the bacillus of Shiga, and the bacillus cyanogenus. There are several clinical types. The term "cholera infantum" is only a generic name, and not a very satisfactory one. The clinical type of the disease, however, may depend less on the variety of the bacteria than on other conditions, such as the state of the mucous membrane or the resisting power of the child's organism.

The peculiar symptoms of the disease are due to absorption of the toxins produced by the bacteria. These substances create a profound impression upon the heart, the nerve centres, and especially the vaso-motor centres. A child previously healthy begins with a rise of temperature a few hours before the vomiting and purging commence, or these symptoms may occur simultaneously. The vomit consists first of food, then of mucus and bile; vomiting may subside and begin again after the administration of food or drink. The stools are abundant, fluid, and frequent, being first brown or yellow, then greenish-yellow, and finally they become watery or serous—rice-water stools. The temperature in mild cases is 102° or 103° F., in more serious ones 104° or 105°, and in fatal cases it often rises to 107° before death. The pulse is rapid, feeble, irregular, and finally almost imperceptible. The respiration is irregular, frequent, or stertorous. The eyes sink into the orbits; the features become sharpened and have an expression of anxiety. The child may be fretful and restless at first, but after a time, especially in fatal cases, there may be convulsions, stupor, or coma. Among the most important clinical signs are the high temperature and the loss of elasticity of the skin, and unless an improvement in these signs can be caused the probability is that the child will die.

*Treatment.*—(*a*) The *vomiting* may be relieved by lime-water, milk of magnesia, a mustard plaster over the epigastrium, a few doses of ingluvin or calomel, or the subcutaneous injection of 1-100th grain of morphine for a child of 6 months, or 1-50th grain of morphine and 1-600th grain of atropine for a year-old child, repeated in an hour. Washing out the stomach is also a valuable proceeding.

(*b*) *Purging.*—Astringents are of little value in these severe cases, especially while the toxæmia and high temperature exist. Should the purging continue after the temperature has fallen to nearly normal, bismuth, aromatic powder of chalk, cinnamon, tannigen, and other astringents may be used. During the acute phase of the disease an attempt must be made to stop the septic process by other means. But I doubt whether we can safely give to a child enough antiseptic to sterilise even a part of the alimentary tract. I think the best way of eliminating the bacteria is by the administration of purgatives and by securing an absence of the nutritive substances on which they flourish so freely. But I always give drugs which tend to reduce the septic conditions—e.g., calomel 1-6th grain, pulvis ipecacuanhæ 1-6th grain every two or three hours; or resorcin 2 grains, tr. opii ½ minim, tr. cardamomi co. 5 minims every two hours. Salol, ½ grain for a child of 6 months, and 2 grains for a child a year old, or beta naphthol, ¼ grain, every two hours, are useful remedies.

(*c*) The *depression* must be fought by the administration of brandy, champagne, musk, camphor, or ether. If they are vomited when administered by the mouth, similar remedies should be given subcutaneously—e.g., ⅓ minim of liq. strychniæ and 5 minims of ether every hour. A mustard plaster applied over the cardiac region is useful. The subcutaneous injection of half a pint of normal saline solution into the tissues of the buttocks or abdominal wall is valuable; it must, however, be injected very slowly, the fluid being allowed to find its way into the subcutaneous tissues by gravity rather than by pressure.

*Dietetics.*—(*a*) *Prophylactic:* Encourage breast-feeding. Avoid weaning breast-fed children in the summer-time. Bottle-fed children should have pure milk made into mixtures of a proper composition and suited to their age. Milk should be filtered through cotton-wool. Avoid improper foods, especially excess of casein and malted foods. Overfeeding must be avoided as carefully as improper feeding. Children become thirsty in hot weather, but they should not be given more food on that account; they should be given plain boiled water or distilled water to quench their thirst. Other prophylactic measures consist of scrupulous cleanliness, especially of the napkins and clothing; protection from flies and from sudden changes of temperature. A thin flannel (not flannelette) garment should be worn next to the skin to protect the abdomen from chill. The feet should be covered. Fresh air and sunlight are essential.

(*b*) *Remedial: Breast-fed children* should be kept from the breast so long as vomiting occurs. They may be fed with a little albumin-water, barley-water, or whey, and stimulants if they seem desirable. After 24 hours' rest of the stomach it is usually safe to resume breast-feeding gradually; at first allowing the child to suck for only two or three minutes at a time, by which means he will get one-fifth to one-fourth the usual amount of milk. He should be fed with albumin-water, whey, or barley-water, with a little meat juice, every two hours until a considerable progress towards recovery is made.

*Artificially fed children.*—Stop all ordinary foods until the vomiting ceases, usually giving a little barley-water or plain boiled water. When this is retained begin to feed cautiously with egg-albumin and lemon-water, whey, white-wine whey, buttermilk, chicken broth or veal broth, a teaspoonful every quarter of an hour. We are cautioned against the use of meat extracts because they have a tendency to increase the diarrhœa. But there are cases where the stimulating effect of creatin is valuable; and, where the child does not react with egg-albumin or whey, I do not think we can do any harm by giving chicken or veal broth, Valentine's meat juice, bovinine, Brand's essence, or hippi in small doses. Albumin water is insipid, but a few drops of bovinine, Valentine, or hippi will improve the flavour, and give to it stimulating properties which are lacking. Children 4 or 5 months old may have a little panopepton or beef-jelly (Mosquera's); children from this age onwards may have starch emulsion (arrowroot being preferable) and white of egg, which is useful in assisting to check protein decomposition and a persistent diarrhœa.

As soon as the acute stage passes off—which is known by the cessation of the vomiting, moderation of the diarrhœa, and reduction of the temperature—we may give dextrinised farinaceous foods, such as Mellin's, with barley-water and whey, or a little cream. Whey and cream mixtures are now very useful; egg-mixtures are especially valuable; and koumiss or fermented milk can be given. In these foods the protein differs from ordinary casein.

| Nutrients per cent. | Protein. | Fat. | Sugar. |
|---|---|---|---|

As the diarrhœa passes off we must consider, if the food has been at fault, how to correct the error. If the fat has been in excess of the child's ability to digest and metabolise it owing to defective assimilation or oxidation, reduce the proportion of fat in the food. Avoid cream mixtures in such cases. Give white of egg and whey, condensed milk and whey, Mellin's food and whey or milk, extract of malt and milk, gradually increasing the strength of the food and adding gravity cream, but not separator cream. If malted foods have caused the diarrhœa avoid them and malt extract also. If casein has been in excess of the child's digestive capacity give egg-mixtures, whey mixtures, cream mixtures, extract of malt and milk. If diluted milk must be used 1 grain of sodium citrate to 1 ounce of food will prevent the formation of curds; or a teaspoonful of extract of malt in ½ pint of warm milk will in 10 minutes alter the casein so that it will be precipitated in fine flocculi nearly as small as those of human milk, and cream can be added to raise the percentage of fat.

### PATHOLOGICAL SECTION.

*Asphyxia under Chloroform.—Lamarckism and Callosities.—Action of Pro- and Anti-thyroid Preparations.*

A MEETING of this section was held on Feb. 21st, Dr. F. W. MOTT, the President, being in the chair.

Dr. A. GOODMAN LEVY (Research Laboratories, University College Hospital Medical School) said that his research was undertaken to investigate the effect of asphyxia in animals under the influence of chloroform in view of a prevalent tendency to attribute a lethal importance to a condition of partial asphyxia induced accidentally in the course of chloroform anæsthesia and termed "intercurrent asphyxia." He considered that under chloroform the cardio-inhibitory reflex was obscured or suppressed by complete asphyxia, and that in conditions of partial asphyxia under chloroform the cardio-inhibitory reflex was variably affected, for it might be either diminished or increased in an apparently fortuitous manner, the intensified form of reaction being, on occasion, of a marked and significant character. Also under ether partial asphyxia affected the cardio-inhibitory reflex in a similar diverse fashion, and the intensified reaction would appear to be no less frequent than under chloroform. In relation to the incidence of fatal suffocation arising from an accidental complete occlusion of the air passages during anæsthesia, it had been stated by Richet in 1895 that chloroformed animals supported asphyxia as well as, if not better than, animals which had not been anæsthetised, and that it was always possible to restore them some minutes after cessation of respiration. That observation did not accord with his (Dr. Levy's) experience, for he had met with cases, both under chloroform and under ether (but more frequently under the latter), in which he failed to restore the heart beat. That subject was, he thought, worthy of investigation, for some of the asphyxial symptoms were not strongly evinced under chloroform, and so there must exist a suspicion that the nature of a suffocative process might not be properly recognised. The following considerations had to be borne in mind in connexion with that matter; that in complete obstructive asphyxia there was a greater deprivation of air than in the case of any of the non-obstructive experiments he had performed, and hence the cessation of respiration came about within a shorter period. Asphyxial spasm was practically suppressed at any higher concentration of chloroform than 1 per cent. The mechanical influence of the asphyxial respirations might induce an earlier fall of blood pressure than in the non-obstructive form of asphyxia. His remarks were, of course, merely suggestive and did not lead to any positive conclusion in respect of the possibility of death from suffocation under chloroform in ordinary clinical conditions. In conclusion, Dr. Levy said that so far as the scope of his experiments extended they did not afford any evidence to justify the assumption that asphyxia, whether partial or complete, was a more serious complication in any important respect under chloroform than under ether

narcosis. In both cases asphyxia was evidently undesirable, and of the two there was evidence that asphyxia under ether was the more active in affecting the respiratory centre.

Mr. S. G. SHATTOCK, in a communication on Lamarckism and Callosities, said that there was a maxim in the investigation of biological problems that they were best approached by a study of their simplest expressions. The question whether acquired characters were transmitted was one still under discussion. It was necessary to define what was meant by acquisition. The acquirement of secondary or external sexual characters at puberty was not a proper instance of it; these were delayed characters only. The term must be limited to an acquisition which was under control, so that the circumstances which called forth such acquisitions being prevented from acting the acquisitions would not arise. That was essentially Lamarck's position. Leismann's category comprised precisely such characters, overgrowth of parts from increased use; atrophy from diminished use; changes due to climatic influence; mutilation. Even in the blind fish among the deep-sea fish from the *Challenger* dredgings it was unproved that the transmitted want of the eyes had resulted from an atrophy acquired by disuse, for such fish were possessed of a phosphorescent organ in the neighbourhood of the eye, the growth of which, Mr. Shattock suggested, was probably correlated with the disappearance of the eye, as the gills of the tadpole disappeared with the growth of the lungs. In regard to overgrowth from increased use, he took the case of the well-known callosities on the sternum, knee, carpus, and other parts of the camel; no simpler example could be given of overgrowth due to increased exercise. The callosities were present on every camel, whether bred in a menagerie or under natural conditions. Were they present at birth? He had critically examined into that in specimens especially obtained from Cairo. In the full-term fœtus there was absolutely no trace of want of hair, or any epidermal thickening in a single one of the proper positions. The character, simple as it was, was not transmitted in spite of its universal and long-continued acquirement; all that was transmitted was the capacity to acquire it should the external conditions come into play. The gluteal callosities in the baboon and certain other monkeys were of a more ambiguous kind. Those were present at birth, but in a certain sense only. He had studied those histologically in the Guinea baboon and in macacus at birth. The skin was quite hairless at birth, but it was particularly thin and devoid of papillæ and glands; the epidermis over it was no thicker than in the loose piliferous skin around. The thickening of the epidermis of the palm and sole of the baboon, &c., at birth was due to the abundant development of papillæ, the intervals between which were filled with it. Those parts were essentially tactile areas, adapted in the first place for arboreal progression. The hairless gluteal areas were not so. By use the epidermis over them became notably thickened; yet that being a proper acquisition from use, was not transmitted. Mr. Shattock provisionally suggested that the thinly skinned hairless districts were related to cutaneous scent gland areas, of which they might be vestiges. Such cutaneous glandular areas were largely found amongst antelopes though not gluteal; in some cases the glandular patch was also piliferous, in others it was bare, and in yet a third there was a thinly skinned, smooth, naked area, the glandular zone being around that. Such a disposition suggested that the hairless area in the monkeys was related to a peripheral glandular zone, and that the hairless area in question was not essentially due to the commonly supposed cause—viz., the sitting attitude adopted by apes; the hairs were not worn down as in the camel; they were congenitally absent.

Mr. W. EDMUNDS read a paper on the Action of Pro- and Anti-thyroid Preparations. He said that it had previously been shown that the administration of thyroideum siccum B.P. caused illness and death in rats, together with changes in the suprarenal glands, and that knowledge was used to test the value of the milk of thyroidless goats in the treatment of chronic thyroid poisoning; as a control the milk of a normal goat was used; it was found that the rats died sooner when fed on the thyroidless milk than with normal milk. It was pointed out that that could be explained by the operation of thyroidectomy on the goat causing a tendency to myxœdema, which might give rise to an antimyxœdemic body, which would be a pro-thyroid body and would aid the thyroideum siccum in causing the death of the rat. The thyroid administration caused exophthalmos which persisted after the treatment was stopped.

Dr. B. H. WEDD read a paper on Multiple Submucous Tumours in the small intestine associated with carcinoma of the larynx, and Dr. A. E. BOYCOTT spoke on Uterine Tumours in Rabbits.

---

## SECTION FOR THE STUDY OF DISEASE IN CHILDREN.

*Exhibition of Cases and Specimens.—The Oculo-motor Type of Polio encephalitis.*

A MEETING of this section was held on Feb. 24th, Dr. E. CAUTLEY, the President, being in the chair.

The following cases and specimens were shown:—

Dr. E. BELLINGHAM SMITH: A case of Spasmus Nutans in an infant aged 11 months. The movements, which were side to side, were first noticed two months ago and were followed in a week by nystagmus. The movements were of only a few seconds' duration and tended to recur every few minutes if the head was unsupported; recently they had become less frequent. They ceased when the child was lying in its cot. The nystagmus was horizontal and more marked in the right eye than the left; it was fine and exceedingly rapid. There was originally a convergent strabismus, and twitchings of the left hand were said to occur.

Dr. J. PORTER PARKINSON: A case of Congenital Dilatation of the Colon in a girl aged 6 years. Except for constipation and occasional colic the child had been healthy from birth. There was no history of consumption or syphilis in the family. The girl was healthy looking and not in the least anæmic. The heart and lungs were normal except for displacement of the diaphragm upwards, which caused the heart's apex to be displaced into the fourth space, and compressed the basis of the lungs. The abdomen at first was greatly distended, measuring 29 inches in circumference, and peristaltic movements of the colon were occasionally visible. It was not tender and was generally resonant. Enemata had brought away enormous quantities of fæces, and the abdominal distension had diminished, so that the measurement was now only 21 inches. The colicky pains had also disappeared. X-ray photographs, taken after injection of bismuth, showed the great enlargement of the colon, and examination of the stomach by auscultatory percussion and other methods suggested that there was some enlargement of that organ.

The PRESIDENT: A case of Cerebral Athetotic Diplegia in a girl aged 2¾ years. The family history was negative, but the mother was only 19 years of age when the child was born. At four months the patient could sit up and this was an important point in favour of the condition being post-natal in origin. She cut her teeth quickly and was said to have talked well at two years of age. She could walk a little by herself last October, but was never able to walk well as her feet turned out. Nine months ago she had a fall, and about that time her back was found curved. For the last four months she had been kept on her back, and for a month or so she was said to have become "strange in her mind." The child was well nourished, and her mental condition was lively but defective. She laughed and cried without obvious cause and could speak only a few words. Her expression was usually rather a vacant smile. The pupils showed no abnormality and there was no nystagmus. The fundi were normal. The palatal arch was high and the teeth were well developed. The head was asymmetrical, 18½ inches in circumference, and was always held a little to one side as if there were slight torticollis, while the chin was receding. The hands showed ataxic and purposeless movements while at rest and some incoördination on movement. There was a little scoliosis in the mid-dorsal region with convexity to the right. The knee-jerks were exaggerated, especially on the left side. The legs were a trifle stiff, and the feet in the position of equino-valgus, but the deformity was easily reduced. The toes were not hyper-extended. The gait was ataxic and slightly spastic, and the right leg was somewhat flexed at the hip and externally rotated. There was also incontinence of urine. The condition was probably due to structural damage,

possibly by mild encephalitis, of the frontal and parietal regions of the cortex.

Mr. D. C. L. FITZWILLIAMS: A case of Congenital Absence of the Pectoral Muscles in a girl, aged 13 years. Both pectoral muscles were absent on the left side, and the chest was flattened. The ribs could be seen as well as felt on that side in consequence. The anterior wall of the axilla was composed of a prominent fold of skin stretching from the front of the chest to the arm. There was an asymmetry about the shoulders, and the left scapula appeared "winged," although the trapezius and serratus magnus muscles seemed normal. No other abnormality had been found, and no history could be obtained of deformity in the family.

Dr. J. W. CARR: A case of Anorexia Nervosa in a Jewess, aged 10 years. Her previous history was indefinite, but she was said to have been healthy until she was five years old, when she lost her appetite, had pain in the stomach after food, and began to waste. Three years ago she was in the Great Ormond-street Hospital; her weight was then 25½ pounds, and she gained 1½ pounds under treatment, but no cause for the wasting was made out. On admission to the Victoria Hospital last September her weight was 26 pounds, and since then she had gained about 1 pound. The child was excessively emaciated, but could walk with ease. She had no appetite and complained of a lump in her throat, which she said prevented food going down. She had been sick nearly every day since admission, often five or six times, usually very soon after taking food. Her temperature was generally subnormal and there was no evidence of disease in any part of the body. Bismuth and radiography showed that there was no obstruction in the œsophagus and no dilatation of the stomach. The tongue was sometimes much furred and sometimes clean. The bowels acted fairly regularly. The treatment tried had included isolation and massage, faradism, feeding by nasal tube, gastric lavage daily, starvation, and chloretone to produce drowsiness, but the vomiting had continued and the general condition remained unaltered.

Dr. A. W. G. WOODFORDE: Specimens from a case of Delayed Chloroform Poisoning in a boy, aged 9 years, who was anæsthetised for the removal of an enlarged gland in the right side of the neck, there being no other signs of disease. The gland was easily removed, anæsthesia lasting in all about 15 minutes. On recovering consciousness he vomited once and passed a comfortable night. On the following day he vomited twice, but took the usual light diet well and appeared to be in a satisfactory condition. Two days later he had slight vomiting on three occasions. The next morning he ate part of his breakfast and was then noticed to be in rather a collapsed state. He reacted well to simple restoratives and slept heavily during most of the day, but was never unconscious. In the evening he vomited and later became unconscious, respiration ceasing two hours afterwards. With artificial respiration the heart continued to beat for five hours after the breathing had ceased. The urine tested shortly before death contained a large amount of (?) acetone. Post mortem, a gross, fatty degeneration was found in the liver, which was golden-yellow in colour, and in the heart, kidneys, and spleen. A few submucous hæmorrhages of small size were seen in the stomach. Caseating tubercle was found in one of the bronchial glands and also in a mesenteric gland. Sections of the liver, heart, muscle, kidney, and spleen all showed an extreme grade of fatty degeneration.

Dr. E. I. SPRIGGS and Dr. J. B. DE W. MOLONY: A case of Angiomata of the Left Loin and Leg in a girl, aged 4½ years. In the left loin there was an irregularly-shaped tumour extending from the eighth rib to 1½ inches below the anterior superior spine and from the mid-Poupart line to the level of the posterior superior iliac spine. It lay superficial to the muscles and was of a soft doughy consistence, giving no expansile pulsation or thrill. In the skin over the tumour were numerous small nævi. There was a similar but smaller tumour in the adductor region of the left thigh, extending backwards towards the fold of the buttock. On the left leg there were five pigmented swellings along the internal saphena vein, each of the size of a hazel-nut and a small non-pigmented mass on the inner surface of the left foot. There were also numerous small nævi scattered over the back in a more or less symmetrical arrangement. The condition was present at birth. Except for enlarged inguinal glands on both sides the child showed no signs of other abnormalities.

Dr. C. RIVIERE: A case of Congenital Aortic Stenosis in a boy, aged 5½ years, with no history of rheumatism. The patient was of normal size, nutrition, and colour. There were no finger-clubbing and no nodules. On the left side of the neck was the scar of a branchial fistula, which was successfully operated upon three years ago. The heart appeared to be of normal size, but the impulse was forcible. There was a thrill over the aortic area but no pulsation. A rough systolic murmur was audible over the whole heart, but of maximum intensity over the aortic area and conducted a long way into the large arteries. The aortic second sound was clear and there was no evidence of a patent ductus arteriosus. The pulse, 100 per minute, appeared to be rather small and soft.

Dr. J. L. BUNCH: A case of Lichen Spinulosus in a child, aged 2½ years. Some months ago an eruption of apparently blackish specks appeared on the chest and later on the shoulders. The lesions present consisted of fine pigmented spines which could be easily removed and left definite depressions marking the openings of the follicles, some of which had become infected by staphylococci. There were also some lesions in the groin, but the characteristics of lichen spinulosus were not so well marked in that situation.

Mr. S. STEPHENSON read a paper on the Oculo-motor Type of Polio-encephalitis. He drew attention to a group of cases of squint in young children, which he believed to be due to polio-encephalitis. Any of the extrinsic muscles of the eye might be affected, but in two-thirds of his cases the external rectus was alone involved. The intrinsic musculature of the eye was seldom attacked. The squint, which was of paralytic nature, was associated in about one-third of the cases with fits, convulsions, stupor, or other symptoms indicative of an affection of the brain. The common form of encephalic strabismus was apt to be confused with the ordinary form of concomitant convergent strabismus, although the age incidence of the two affections was different. For purposes of differentiation a careful examination of the corneal reflexes was all-important.

The cases and paper were discussed by the PRESIDENT, Dr. H. SKELDING, Mr. FITZWILLIAMS, Dr. L. G. GUTHRIE, Dr. F. LANGMEAD, Dr. C. R. BOX, Dr. C. W. CHAPMAN, Dr. F. PARKES WEBER, Dr. J. BLUMFELD, Dr. BELLINGHAM SMITH, Dr. J. D. ROLLESTON, and Mr. J. P. L. MUMMERY.

## OTOLOGICAL SECTION.

*Malignant Disease of Lateral Wall of Naso-Pharynx.—Report and Exhibition of Cases.*

A MEETING of this section was held on Feb. 17th, Mr. ARTHUR H. CHEATLE, the President, being in the chair.

Dr. EDWARD LAW reported the termination of a case of Malignant Disease originating in the region of the Eustachian tube, early symptoms of which were deafness and discomfort in the ear.

Mr. WILFRED TROTTER gave a brief summary of the principal features of Malignant Disease of the Lateral Wall of the Naso-pharynx, as exemplified in eight cases which he had operated upon, including Dr. Law's patient. In five or six of the cases the tumour was an endothelioma originating about the Eustachian tube, and in them the symptomatology was remarkably uniform. 1. Pain was the first symptom, and lasted some months. The diagnosis at this stage was generally trigeminal neuralgia. 2. Deafness of the type produced by Eustachian obstruction, which in some instances could be temporarily relieved by means of the Eustachian catheter. Failure to give relief had led to further examination and eventually to the discovery of the disease. 3. An abnormality of the soft palate was sooner or later noticeable; this was raised but could not be relaxed on the affected side, owing no doubt to infiltration of the levator palati. 4. In the later stages œdema of the soft palate and adjacent pharyngeal walls appeared. 5. In none of these cases was nasal obstruction a striking symptom. Access to the disease was gained by an osteoplastic operation, the essence of which was reflection of the upper jaw and malar bone in a flap. The base of the skull and lateral wall of the naso-pharynx were thus brought well into view. In some cases it had been necessary to ligature the internal or common carotid artery. The patients usually recovered well from the operation, but none had survived without recurrence of the disease longer than 15 months, a circumstance which emphasised the importance of early

diagnosis.—Mr. HERBERT TILLEY recorded his experiences of similar cases.

Mr. SYDNEY R. SCOTT reported a case of Fistula of the Superior Semicircular Canal on the left side; bilateral radical mastoid operation; instrumental exploration of the left vestibule; total vestibular ablation reactions on left side. One of the principal points of interest was the evidence which indicated localisation of disease without involvement of the cochlea.

Dr. H. J. DAVIS showed: 1. A case of Caries and Necrosis of the Temporal, Parietal, and Occipital Bones following mastoiditis due to scarlet fever in a girl aged 5 years; operation; recovery. 2. A case of Extra-dural Abscess of the Posterior Fossa tracking through the jugular foramen into the neck; sloughing of middle third of internal jugular vein; operation; recovery. 3. A case of Acute Vertigo with repeated falls, always to the left, during the last two months. He asked for an expression of opinion as to whether the disease was labyrinthine, intra-cranial, or due to hysteria. The patient had had mastoid suppuration, complicated by the presence of nystagmus, giddiness, headache, epileptiform fits, and complete left hemianæsthesia. The caloric reactions were negative on the left side, but positive on the right side, and this pointed to an organic lesion.—The case was discussed by several members, who agreed that the evidence pointed to an organic lesion occurring in a so-called hysterical patient.

Dr. W. H. KELSON exhibited a patient with a very Unusual Swelling in the Tympanum.

Dr. DAN MCKENZIE showed a boy upon whom the Complete Mastoid Operation had been performed 18 months previously, the bone forming the so-called facial spur having remained bare ever since that time.

## SOCIETY OF TROPICAL MEDICINE AND HYGIENE.

*Malaria.*

A MEETING of this society was held on Feb. 17th with Professor RONALD ROSS in the chair.

Professor ROSS read a paper on Some Enumerative Studies on Malaria, Blackwater Fever, and Sleeping Sickness. He said that by enumerative methods he meant the systematic counting of the numbers of organisms present in men or animals infected with given parasites. The object was threefold: first, to ascertain the correlation, if any, which existed between such numbers and the various symptoms; secondly, to determine with more exactness the effect of various therapeutic agencies; and thirdly, to obtain more light upon the general phenomena of the parasitic invasion. The mere detection of parasites was not enough. For further knowledge they must count, measure, and compare, with the ultimate object of learning how to cure. For example, a pigeon contained swarms of halteridium and remained apparently quite well, but the same number of Plasmodium falciparum in a man made him seriously ill. Why and how was this? Again, why did plasmodia appear and disappear so frequently? Why were the sexual forms not always present? Why did the numbers of leucocytes vary? and so on—questions which they could not even attempt to answer without very careful measurements. Again, regarding experimental therapeutics, the method in use was to try whether a given line of treatment abbreviated sickness or prolonged life in a number of cases. By counting the parasites before and after a dose of a drug, however, they could now often obtain a much more exact criterion of its effects. In short, without such countings they could seldom reach any real proof on a number of most important propositions. They might almost say that the history of what was called medical science was largely a history of defeats due principally to the absence, or impossibility, of numerical exactness—to mere qualitative observation and to insufficient sampling. Of course, parasite counts had been made previously, and they had attempted nothing more than making them methodically. Dr. David Thomson had studied 33 cases of malaria—one of P. malariæ, eight of P. vivax, and 24 of P. falciparum—and made daily counts, numbering about 600 altogether. It was found that the numbers of asexual forms diminished gradually after the febrile period until about the middle of the apyrexial interval was reached, after which they increased gradually again, until they became numerous enough to cause a relapse. Dr. Thomson could, indeed, foretell a coming relapse by this gradual increase. There was no sudden and absolute disappearance of the asexual forms during the rally, as they had previously thought occurred. In regard to treatment of malaria, it was shown that quinine was not immediately lethal to all the parasites; but they could not plot the curve showing the progress of reduction. Whether the lethal action of the drug became more and more or less and less marked day after day they could not determine; and yet that was precisely the point requiring determination in order to say how long the treatment must be continued to obtain total extirpation. Methylene blue and soamin had little effect on the asexual forms; but Dr. Thomson thought that the former affected crescents—which remained very refractory to quinine. Referring to blackwater fever, Professor Ross said that one of the cases of malaria suffered from typical blackwater fever while under study in hospital. The patient had three distinctly pyrexial periods, all differing as to three things—plasmodia, fever, and hæmoglobinuria. The first attack showed plasmodia with the characteristic plasmodium fever and no hæmoglobinuria. The second showed no plasmodia, but typical blackwater fever and blackwater. The third showed no plasmodia and no blackwater, but a typical blackwater fever alone. What was the cause of the fever during the second and third attacks? It could not have been the hæmoglobinuria, because that was entirely absent during the third attack. In blackwater fever, therefore, there must be some subterranean factor at work, some process different from the ordinary processes of ordinary malaria. In regard to sleeping sickness a periodic cycle was shown. On Dec. 4th, 1909, a young man, aged 26 years, was admitted into hospital for trypanosomiasis contracted three months previously in N.E. Rhodesia. Regular daily counts of his trypanosomes were commenced by Dr. David Thomson on Feb. 14th, 1910, and quickly revealed a phenomenon not previously clearly observed—namely, that the parasite curve rose and fell regularly about once a week. The discovery of the cycle enabled them to test the effect of treatment with some accuracy. The case was unfortunate because of the great effect of atoxyl on his eyes, but they were obliged to give it frequently nevertheless. On April 5th four grains were injected at the commencement of a parasitic rise; but the rise continued apparently unchecked. They could not say that following doses produced any marked reduction, though, of course, the parasites might have become more numerous without them. At the end of the case the curve presented precisely the same appearance as at the beginning. Quinine, methylene blue, trypan red, succinamide of mercury, izal oil, potassium iodide, trypsin, and amylopsin had no marked success, though the two first-named seemed to benefit the œdema to some extent.

Dr. ROBERT T. LEIPER, helminthologist to the London School of Tropical Medicine, contributed some notes on the Presence of a Lateral Spine in the Eggs of Schistosomum Japonicum; and Dr. N. F. SURVEYOR, professor of bacteriology, Grant Medical College, Bombay, communicated a few observations on the Cultural Characteristics of a Variety of the Streptothrix of White Mycetoma.

CLINICAL SOCIETY OF MANCHESTER.—A meeting of this society was held on Feb. 21st, Mr. J. Howson Ray, the President, being in the chair.—Dr. George R. Murray read a paper on the Treatment of Some Diseases of the Lymphatic Glands and Spleen. In the treatment of Hodgkin's disease he laid stress on the necessity of carefully examining the mouth, ears, nose, and skin, and the insisting on the avoidance of all mental and bodily strain. The ordinary lines of treatment by drugs he referred to, and discussed the advantages and disadvantages of surgical treatment—removal of enlarged glands—and treatment by X rays. His experience of surgical treatment had not been very encouraging, and unless there was pressure on important nerves or vessels by the enlarged glands he would refrain from advising its adoption. The X rays were the most valuable means at our disposal for the treatment of these cases. He had seen most satisfactory results follow their use, but was of opinion that the best

results would be got if arsenic was administered at the same time. The rays reduced the gland enlargement as nothing else could, but unfortunately the patient's general condition did not show a corresponding improvement. By whatever line of treatment adopted, however, cure could not be attained, but merely a keeping of the disease under control. The apparatus used should be a powerful one, and the rays given two or three times a week for periods depending on the condition of the patient. Several cases were quoted, amongst them being that of a lady with marked enlargement of the mediastinal glands, where the rays had produced a very wonderful improvement in the condition of the glands, her general condition, however, being very little better. In leukæmia, when there was a rise of temperature, the patient should be absolutely confined to bed and great care observed to avoid injury to the spleen. He strongly urged open-air treatment for these cases. Arsenic should be given in large doses; in one case he had given 25 minims of the Fowler's solution three times a day. The X rays were of value, leading to a surprisingly rapid reduction in the size of the spleen and markedly controlling the excess of the white blood corpuscles. The applications should be persisted with for two or three months, and then given once a month. Here, again, the rays did not lead to a cure, and he had observed that where relapses occurred they had frequently proved valueless. In lymphatic leukæmia the acute cases ran a very rapid course and the chronic ones were very protracted. Cases were quoted to prove that in this condition the X rays were of little value. They certainly reduced the white blood corpuscles, but at the same time there was a very marked reduction of the red. In splenomegaly the X rays were of no value. He thought excision of the spleen held out the best chances for the patient. Where ascites was present tapping must be resorted to.—Dr. C. H. Melland said that his experience of the removal of one set of glands in Hodgkin's disease was that it frequently led to the lighting-up of the disease in other glands. Arsenic had given him excellent results. It should be given in large doses, stopped for a while, then large doses again, and finally the patient kept on a course of small doses. X rays, he thought, were effective, but he preferred to start with arsenic, and when this appeared to be failing in its effect then go on to the rays. In leucocythæmia he regarded arsenic as invaluable. He had seen the leucocytes reduced in ten months from 150,000 to 8000 per cubic millimetre. The reduction, too, was usually accompanied by an improvement in the general condition of the patient, a fact which was often absent in Hodgkin's disease. In splenic anæmia he thought arsenic should be given in increasingly large doses. In one case under his care he had observed the reduction in the size of the spleen to one half what it was when the arsenic was started, and this in two months, and the accompanying anæmia had entirely disappeared. A recurrence of the condition would make him seriously consider the advisability of surgical interference.—Dr. P. R. Cooper said he regarded lymphadenoma as being very closely allied to lymphosarcoma, and acting on this opinion he had some years ago treated an advanced case of the former with injections of Coley's cancer fluid. He started with injections of half a minim and finally was giving five minims. The injections had on two occasions been followed by serious collapse. He was of opinion that treatment with vaccines would most probably in the future prove to be of value. — The President briefly referred to the effects produced by the injection of Coley's fluid. He had seen collapse follow the injection of half a minim, while two or three minims had no effect.—Dr. A. A. Mumford asked Dr. Murray if the X rays had proved of any value in the treatment of enlargement of the thyroid gland. —Dr. Murray, in reply, said that he had not observed the effect of surgical treatment referred to by Dr. Melland, but would bear it in mind. He pointed out to Dr. Cooper that the structure, microscopically, in lymphadenoma and lymphosarcoma had been definitely proved to be entirely different. The X rays had proved of no value in the treatment of enlargement of the thyroid.

MEDICO-CHIRURGICAL SOCIETY OF GLASGOW.—A meeting of this society was held on Feb. 17th in the Victoria Infirmary, Professor R. Muir, the President, being in the chair.—Dr. A. Napier described the Treatment of Phthisis Pulmonalis as carried out in his wards.—Mr. A. E. Maylard showed a series of Abdominal Cases illustrating the following conditions:—(*a*) Congenital narrowing of the pyloric orifice treated by gastro-jejunostomy. (*b*) Hypertrophic stenosis of the pylorus in the adult; pylorectomy with gastro-jejunostomy for supposed malignant disease. (*c*) Hour-glass contraction of the stomach treated by gastro-gastrostomy. (*d*) Intractable gastric neuroses treated by exploratory gastrotomy. (*e*) Tuberculous cæcum—excision and implantation of ileum into ascending colon by invagination. (*f*) Carcinoma of colon—excision—continuity established by intestinal invagination. (*g*) Carcinoma of colon—inoperable—short-circuiting by intestinal invagination in place of artificial anus. (*h*) Acute intestinal obstruction—fæcal vomiting—evacuation of contents of intestine and introduction of magnesium sulphate into the bowel. (*i*) Appendicitis with abscess—appendicectomy and swabbing of abscess cavity with pure carbolic acid. (*j*) Tuberculous peritonitis—laparotomy—removal of fluid and exploratory manipulation of parts. (*k*) Uterine and ovarian tumours removed by subumbilical transverse incision. (*l*) Invagination of divided ureter into bladder. (*m*) Transperitoneal nephrectomy by transverse incision. (*n*) Lipectomy for pendulous abdomen and ventral hernia—removal of 10 pounds 11 ounces of fat by a 21-inch transverse elliptical incision. (*o*) Abdominal cicatrices after transverse or oblique division of the rectal sheaths and recti muscles.—Mr. R. H. Parry showed cases to illustrate Points in the Surgical Treatment of (*a*) Torn Cartilage in Knee-joint; (*b*) Exophthalmic Goitre; (*c*) Fractures into Joints; (*d*) Gangrene of Gall-bladder; and (*e*) Duodenal Ulcer.—Dr. J. Grant Andrew showed (*a*) Cases of Renal Calculi, with Skiagrams; (*b*) Two Children suffering from Infantile Spastic Paraplegia who, prior to orthopædic treatment, were unable to walk; and (*c*) an Infant who has been Operated on for Congenital Hypertrophic Stenosis of the Pylorus.—Dr. Robert B. Carslaw showed (*a*) a patient operated on three months ago for Perforation of Pyloric Ulcer (Excision of Ulcer, Pyloroplasty), who developed empyema suddenly after two months of good health; (*b*) Card Specimens—(1) Acute Carcinoma of the Breast removed from a young woman, aged 29; (2) X Ray Photographs of Two Cases of Tuberculosis of the Acetabulum, with Pathological Dorsal Dislocation of the Head of the Femur (photographs taken before and after operation).—Dr. A. Brown Kelly showed cases presenting the following conditions:—(*a*) Double Abductor Paralysis; (*b*) Pharyngeal and Laryngeal Nystagmus; (*c*) Cornua of Hyoid Projecting into Pharynx; (*d*) Cicatricial Stricture of the Œsophagus; (*e*) Submucous Cleft Palate; (*f*) Keratosis of Pharynx and Larynx; and others.—Dr. A. N. M'Lellan showed (*a*) a patient operated on for Extra-uterine Pregnancy of the Right Tube, in whom the left tube was distended with blood-stained fluid and closed; (*b*) a case of Carcinoma of the Body of the Uterus; (*c*) a case of Fibroma of the Left Ovary with extensive adhesions to bowel and pelvic floor; large accumulation of fluid in pleural and peritoneal cavities, which was removed on several occasions by tapping; removal of tumour, followed by complete disappearance of fluid from both cavities; patient now in good health.—Dr. Albert A. Gray showed (*a*) microscopic sections showing the organ of Corti; (*b*) microscopic sections showing the Cochlea of a Deaf-mute; (*c*) microscopic sections from a case of Oto-sclerosis; (*d*) macroscopic specimen showing Fixation of the Stapes in Oto-sclerosis; and (*e*) family tree showing the Influence of Heredity in Oto-sclerosis.—Dr. Hugh Walker showed some Ophthalmic cases.—Dr. John Anderson showed pathological specimens illustrating some of the Enlargements of the Kidney.—Dr. D. O. MacGregor showed a series of skiagrams illustrative of various medical and surgical conditions.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Feb. 17th, Dr. J. Dobson being in the chair.—Mr. H. Collinson read a paper on the Acute Aspects of Appendicitis in Children.—Dr. T. Churton showed two cases of Graves's Disease and made some comments on the prognosis, drawing attention to the fact that it was in many cases favourable. He related the case of a woman who had been under his observation for 33 years. She recovered from the first attack in 12 years; less completely from a second attack; and died in 1910 from (it is said) heart disease and dropsy at the age of 54 years. Another patient still under observation had been free from symptoms for 11 years.—Dr. T. Wardrop Griffith gave a short demonstration of the information obtained by the use of the clinical polygraph in cases of actual and of apparent pulsation of the liver, in connexion especially with

cardiac disease. Two cases were especially commented on in which there was great hepatic enlargement. In one of these in which there was a pulse of the continuously irregular type, with a jugular pulse of the ventricular variety, there was extreme hepatic expansile pulsation which was shown to be also of the positive or ventricular character. In another case in which the enlargement was quite as great the pulsation of the liver was shown to be apparent only, and due to an upward drag on the liver exercised on that organ by the contraction of the ventricles. In a third case an auricular as well as a ventricular wave was shown. The bearing of these observations on diagnosis was briefly commented on.—Mr. H. Secker Walker showed a case of Chronic Glaucoma affecting both Eyes, for which Herbert's small scleral flap operation had been done ten weeks previously with successful results. He also exhibited a case of Excision of the Lacrymal Sac for Chronic Dacryocystitis.—Mr. J. A. Coupland showed a girl, aged 18 years, with an Ulcer exposing the Inner End of the Right Clavicle. The ulcer was of 17 months' duration. It had firmly healed under complete rest with fixation of arms, but recurred in two months. The ulcer showed no characteristics of syphilis or tubercle and did not react to antisyphilitic treatment. It was suggested that the ulcer was artificially produced by the patient herself. —Mr. W. Thompson showed a boy, aged 12 years, in whom four years ago the greater part of the right tibia was removed for acute osteomyelitis. The upper epiphyseal line of the tibia had been destroyed and it was three inches shorter than the other tibia. The fibula was half an inch shorter than the other and had overgrown the tibia both above and below.—Mr. W. Gough showed a Villous Tumour removed from a woman who had had several attacks of painless, profuse, paroxysmal hæmaturia. Through Nitze's cystoscope a small tumour was seen at the left ureteral orifice. A large Kelly's cystoscope was then passed and the tumour was avulsed by means of a pair of long-nibbed forceps. Removal left only one small raw point.—Mr. H. Littlewood and Mr. S. W. Daw showed a boy, aged 12 years, in whom there was a massive Keloid of the Neck following burns from ignition of a celluloid collar two years ago. The tumour began to appear as the scar was healing. —Mr. G. Constable Hayes showed a patient, aged 24 years, who had had a Discharge from both Ears from Childhood. She had suffered from snuffles and sores around the mouth as a baby (marked scarring at angles of mouth). The right ear showed complete destruction of the membrana tympani and ossicles. The opening of the Eustachian tube was seen in the middle ear. Watch was heard at 5 inches. The left ear showed an aural polypus presenting at the external auditory meatus, with its origin from the attic. Watch was heard at 15 inches. The nose showed extreme atrophy of ethmoid with rhino-pharyngitis sicca.—Mr. H. Collinson showed a case of Bismuth Poisoning after the use of Stiles's paste.—Cases and specimens were also shown by Dr. E. F. Trevelyan, Dr. J. Stewart, Dr. J. B. Hellier, Dr. R. A. Veale, Mr. Michael A. Teale, and Dr. W. H. Maxwell Telling.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Feb. 16th, Mr. A. W. Cuff, the President, being in the chair.—Dr. John Robertson read a paper in which he stated that there had probably been no greater change in the whole range of medicine than that which had taken place in their views in regard to the nature of infection and the methods by which it was conveyed from one person to another. They now recognised that from 60 to 70 per cent. of all the deaths were due to processes which were known as infective, while of the remaining ill-defined causes of death many were of similar origin. There was still a group of infective diseases, of which measles and small-pox were types, in regard to which their knowledge was very incomplete, as they did not know how the infection was given off from the infected person. They had, therefore, invented as an explanation the theory of aerial convection. Clinical and bacteriological investigation had, however, given reliable information as to how the infection in most of the other diseases was conveyed either directly or indirectly. Careful observations in fever hospitals and in private practice had demonstrated beyond doubt that in the majority of diseases the infection was transported from one to another directly or indirectly, and that passage through the air did not play the part which it was at one time thought to play. While this was so in practice it could be demonstrated that in the act of loud talking particles of saliva were ejected from the mouth and carried in the air to distances of 30 or 40 feet. It was, therefore, probable that this projection of infection should be taken into consideration in dealing with cases where coughing or sneezing was present, such as occurred in measles, whooping-cough, and tuberculosis of the lung. No two diseases could be regarded as alike in the way in which the infection was spread. Carrier cases were now a recognised source of infection. Dr. Robertson thought that they played a very much less important part in practice than theoretically they should play. The problem of infection spread by flies, mosquitoes, fleas, &c., was also dealt with.—Dr. Arthur J. Hall showed a case of combined Posterior and Lateral Sclerosis (Ataxic Paraplegia) in a man aged 23 years. The symptoms, which began 18 months ago, consist of marked ataxia with weakness in the legs and pain in the knees. The gait is very ataxic and is associated with some jerkiness of movement and slight tremors at times. The eyes are normal in every way, also the head and neck and upper limbs. Romberg's sign is well marked; patellar jerks much exaggerated; toe extension on both sides; no true ankle clonus; no tenderness; no definite alteration of sensation; sphincters normal; no family history of similar cases; no syphilis; no etiological factor discovered.

BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Feb. 23rd, when a demonstration of Kinematographic Microscopy was given by Dr. E. Burnet of Leamington. The films exhibited showed trypanosoma Brucei, trypanosoma Lewisi, spirochæta gallinarum, spirochæta pallida, the organisms of relapsing fever, and spirochætæ of Vincent. The demonstration was a most interesting one, and a large audience listened with the greatest interest to the explanation given by Dr. Burnet of the various points shown by the films. A hearty vote of thanks to the demonstrator concluded the proceedings.

# Reviews and Notices of Books.

*Manual of Medicine.* By THOMAS KIRKPATRICK MONRO, M.A., M.D. Glasg., Professor of Medicine, St. Mungo's College; Fellow of, and Examiner to, the Royal Faculty of Physicians and Surgeons, Glasgow; and Physician to the Glasgow Royal Infirmary. Third edition. London: Baillière, Tindall, and Cox. 1911. Pp. xxii.–1023. Price 15*s.* net.

THE author of this well-known manual has in this new edition thoroughly revised it from beginning to end. Many details have been altered, and extensive additions been made to the subjects of dysentery, syphilis, cardiac arrhythmia, the cerebro-spinal fluid, epidemic anterior poliomyelitis, enteroptosis, certain affections of the skin, and food poisoning. It now offers to the student of medicine an exposition that is thoroughly in accord with the best teaching of the present day. We have before reviewed the work very favourably, and the present edition again is one that can be thoroughly recommended to the student. We shall in this notice lay more stress on the new matter.

Enteric fever is lucidly described, but in the section on the etiology we find no mention of the great epidemic in England caused after the termination of the South African war by the agency of the blankets that had been used by our sick in hospital in South Africa. More stress might also have been laid on the agency of carriers of the disease, such a fruitful source in India of its propagation. Amongst the antiseptic drugs mentioned, that introduced to the profession by Sir Robert Simon, namely, oil of turpentine, is not spoken of. This drug most certainly, in the experience of those who have tried it, improves the pulse and the state of the evacuations, and is also an extremely good prophylactic against intestinal hæmorrhage. The treatment laid down for pneumonia is excellent, especially that with respect to the use of alcohol and strychnine. We would like to have seen some remarks concerning the beneficent use of that old and now too generally discarded remedy, antimony. In

the section on acute rheumatic fever there is no mention of the prophylaxis as regards the supervention of endocarditis advocated by Dr. R. Caton of Liverpool.

Dysentery is in this edition considered more definitely under the heads of bacterial and amœbic dysentery. The post-mortem lesions of the latter form are briefly but well described, as are also the symptoms. The treatment is thoroughly in accordance with the rules of our American *confrères* in that the use of enemata is especially indicated. There are, we notice, certain important omissions in the remarks on the treatment of blackwater fever, which should be remedied in a future edition. Thus no mention is made of Sternberg's mixture of bichloride of mercury and bicarbonate of soda, which has proved of such value at the hands of many physicians, and especially the urgent necessity of giving frequent rectal enemata, six to eight ounces at a time, of normal saline solution, until the hæmoglobinuria ceases. This has certainly proved a most successful treatment. It should be commenced early. The author, in his remarks on syphilis, draws attention to the Wassermann reaction, showing its value as a guide to early treatment, and in the determination in any given case whether specific treatment should be continued or not. He also remarks on the value of the new remedy "606."

In the section on circulatory disorders an excellent diagram is given of the relations of the heart and great vessels to the lungs and thoracic wall. Arrhythmia receives a much more extended notice in this edition than in the last. The researches of Gaskell and James Mackenzie receive due acknowledgment, and the author in his remarks on this symptom has included everything of importance.

The section on abscess of the liver is excellent. The author's remarks are thoroughly up to date. The work of Major Leonard Rogers, so well known in India by his researches on tropical medicine, is recognised; this latter observer has taught us how to diagnose amœbic hepatitis in its pre-suppurative stage, and has reintroduced the treatment by ipecacuanha, advocated by the late Surgeon-General W. C. Maclean. He has also successfully treated in many cases deep-seated abscesses by injecting 30 grains of bihydrochloride of quinine in two ounces of water, after evacuation of the pus by the aspirator.

In the description of epidemic anterior myelitis the author has furnished us with one of his best sections; and in its concise, but at the same time complete, portrayal of the disease the student will find one of the best expositions we know. A new feature of the work is the section on the cerebro-spinal fluid; here the changes in the fluid in disease, the method of puncture, and its value as a therapeutic agent are fully discussed. Finally, amongst other additions to the work we would emphasise the fuller treatment of the subject of enteroptosis and of certain affections of the skin, whilst the whole section on the affections due to food poisoning could not be better described.

By the use of a larger page the author has managed not to make his work too cumbersome despite its valuable additions. It is an excellent treatise.

---

*Gynecological Therapeutics.* By S. JERVOIS AARONS, M.D. Edin., M.R.C.P. Lond. With Foreword by Sir J. HALLIDAY CROOM, M.D. Edin., F.R.C.P., F.R.C.S. Edin. London: Baillière, Tindall, and Cox. 1910. Pp. 178. Price 5*s.* net.

IN the opinion of the author, most of the text-books on gynæcology treat of the subject too much from the purely surgical point of view, and he has therefore written this book dealing with the medical aspect of gynæcology, and containing an account of such methods of treatment as he has had personal experience of. The book contains a large amount of practical information of a useful character and a number of prescriptions which cannot fail to be of help to the practitioner.

There are, in our opinion, one or two omissions: thus in the treatment of inversion of the uterus the author, although he mentions the possibility of having to amputate the uterus, says nothing of the various forms of hysterotomy which should, of course, be tried first. The objection raised to the use of a rubber cup-and-stem pessary for prolapse of the uterus does not, we think, hold good; the new form of ring-and-stem rubber pessary is undoubtedly the most comfortable for the patient, and the fact that the stem is pliable prevents the instrument from causing pain if the patient inadvertently sits upon it.

There is a want of order in the arrangement of the book which does not increase its value. Thus, the chapter on Vaccines and Sera is followed by one on Pelvic Peritonitis. The statement on p. 163, that if the uterus of a parous woman be acutely anteflexed the utero-sacral ligaments are shortened by inflammatory infiltration, does not correspond with our clinical experience, nor with the condition of the utero-sacral ligaments as revealed by operation in the majority of these cases. Eau de Cologniensis is a curious term; the only name for this liquid known to us, apart from eau de Cologne, is spiritus Coloniensis.

Dr. Aarons evidently believes in the leverage action of the Hodge pessary. We wish he had attempted to give a satisfactory explanation of the mechanics of such an action, if it exists.

---

*Handbuch der Vergleichenden Physiologie.* Herausgegeben von HANS WINTERSTEIN. Band II.: Physiologie des Stoffwechsels (Erste Hälfte); Lieferungen 6, 7, 9, and 13. Band III.: Physiologie der Energieproduktion (Zweite Hälfte); Lieferungen 8, 10, and 11. Band IV.: Physiologie der Reizaufnahme, Reizleitung, und Reizbeantwortung (Erste Hälfte); Lieferung 12. Jena: Gustav Fischer. 1910. Each Lieferung 5 marks, and pp. 160.

THE four parts of Vol. II. deal with the Physiology of Metabolism. It is impossible to do justice to the colossal amount of labour bestowed by Professor Biedermann on such an immense subject. His researches on electrical phenomena manifested by living beings have become classical, so have his researches on colour changes in frogs, and now from the seemingly small—yet important—beginnings on the digestion in the insecta, published some years ago in *Pflüger's Archiv*, we have this magnificent compilation of all that relates to the metabolism, not in one animal, but in all invertebrates, beginning with the lowest. The ripe and extensive knowledge of zoological details, the excellent illustrations of gross and minute structure, and the multifarious types under review, coupled with the careful account of the physiology of the processes of the capture, reception, digestion, and assimilation of food in such a variety of animals, command not only our admiration for the thoroughness of the author's researches into this vast subject, but also for his unwearied perseverance in collecting such a mass of facts as were certainly never before included in any one monograph on metabolism and allied subjects. Professor Biedermann has laid a broad basis for the foundation of the study of the comparative physiology of metabolism. The four parts before us deal with the cœlenterata, including an elaborate account of symbiosis with algæ, both in cœlenterates and in turbellarians. Then follows a graphic account of the nutritive processes in worms in all their varied forms, including a discussion on Bunge's fertile suggestion of the resemblance between the conditions that obtain in the intestine and those in which anaerobic bacteria flourish. Naturally the leech and the earthworm come in for full treatment. As to the latter, regret is expressed that in spite

of the work of Darwin and many other observers we are still very imperfectly informed regarding its digestive activities. The echinoderms are fully treated, and we are glad to see justice done to the excellent work of Preyer and of Jennings. Next follows digestion in the crustacea, spiders, insects, and the wonderful changes that necessarily occur in the digestive organs from the caterpillar to the imago stage. The mollusca, including the cephalopods and the gasteropods, are dealt with in a similarly comprehensive and exhaustive manner. We strongly commend the study of the questions dealt with to zoologists, for Professor Biedermann has linked up the facts of structure with their uses in a manner never before attempted on a scale so wide and so suggestive. Specially interesting is the extensive discussion of the glycogen problem in the mollusca and the varied and important functions performed by the "liver." Towards the end of the thirteenth part the author begins the study of digestion in vertebrates, including fishes, amphibia, and reptiles. To put in another way some idea of the "gründlich" character of Professor Biedermann's contribution we may say that this section has already extended to 1144 pages of text and illustrations.

The first part of Vol. III. deals with all that relates to animal heat. It is from the pen of one of the most distinguished of living physiologists, Robert Tigerstedt of Helsingfors, whose text-book on physiology, originally written in German, has been translated into English. The monograph on heat is, like the succeeding monograph by S. Garten on "The Production of Electricity," a type of what a monograph ought to be. These two contributions will form the storehouse to which most investigators interested in these subjects will refer. To the work of English observers full justice is done, but in dealing with the electrical currents of the eye, long ago investigated by Dewar and McKendrick, it is perhaps a pardonable mistake that the latter name appears as Kendrick (p. 163), although it is correctly given in the literature index (p. 220). The illustrations are of a high order, and are well executed, soft, and pleasant to the eye. A very full account is given of the histology of the electrical organs. Some of the figures are original, and, of course, Ballowitz is largely drawn upon.

The latter half of the tenth and the greater portion of the eleventh part are devoted to the Production of Light. As set forth by Dr. E. Maugold the subject is presented in an attractive essay. It is a far cry from Aristotle to Pflüger, but the mentor of Alexander knew many things, including the fact that under certain conditions dead flesh became luminous. To come to later times, Fabricius ab Aquapendente of Padua observed luminosity for four days in a dead piece of lamb, while Boyle, by means of his air pump, noticed that the light diminished with the withdrawal of air and became brighter on its admission. Molisch, however, in recent years is the chief authority on luminous bacteria. In 1907 28 well-defined species of luminous bacteria were described. The common one on dead meat is Bacterium phosphoreum. There does not seem to be any reference to Sir James Dewar's recent experiments on the effect of very low temperatures on these organisms, though Macfadyean's work is referred to. A systematic account, illustrated by numerous figures, is given of the animals from protozoa upwards which exhibit luminosity, and in those that possess special luminous organs the minute structure of those organs is fully given. The latter half of the memoir is devoted to the peculiarities of the light itself—its colour and spectrum, the conditions of bio-luminescence, and the theory of light production—its relation to heat production, and how it is influenced by various conditions and stimuli, and especially its relation to oxygen. Reproductions of photographs taken by means of luminous bacteria by Molisch are given, but we hardly think that they are as good as those obtained by Professor P. Dubois of Lyons in the well-known instance of the bust of Claude Bernard. The production of light in plants is also included, with over 600 references to the literature. The remaining portion of the eleventh part is devoted to the Physiology of Form, by H. Przibram of Vienna, well known for his researches on the reproduction of organs and his studies in regeneration in animals. Throughout the work maintains its high standard, and must prove a boon to both physiologists and biologists.

Before any one of the four volumes is complete we are introduced to Part 1 of Vol. IV. Here a well-merited reference to the commanding and illuminating results of Sherrington's contributions to the physiology of the sensory receptor fields, as well as to the doctrine of specific energies of Johannes Müller, precedes a general account of the functions of the central nervous system; after which the author, Dr. S. Baglioni of Rome, proceeds to deal with protozoa and plants—regarding both from the point of view of the comparative neurologist. The careful reader will note that the author excludes "reflex-vorgänge"—i.e., reflex processes from the well-known responses that occur on the application of stimuli to plants and lowly animals. He reserves the term "reflex" for processes where a "central organ" is present. Myophanes or myoids are known to exist in stentor and vorticella, but according to Neresheimer there are neurophanes as well, which lie between the contractile fibrils and react differently from the myoid fibrils. The transmission of the excitatory state in plants is chiefly through the fine plasmatic bridges between the adjacent plant cells which seem to make the plant itself a unit.

Hertwig and others long ago showed the presence of a nervous system in certain of the cœlenterates—e.g., Medusæ. The author gives an elaborate account of the phenomenon elicited by the application of noxious and useful stimuli to polyps, such as hyola, and also of the experiments of Loeb on regeneration of parts in cerianthus, the study of tropisms, and the excellent work of Jennings on the movements of the lowest animals—movements which Loeb thought did not imply the presence of a nervous system. There is a full discussion on the function of the nervous system in polyps and actinia and their allies. The classical work of Romanes on Medusæ is fully gone into and so is that of Yerkes on Gonionema. The author quotes liberally from Romanes. Verworn denied the existence of a nervous system in ctenophora, although Nagel postulates its existence. A very full account is given of the nervous system in worms and of the very numerous experiments that have been made on them by Retzius, Friedländer, and Biedermann. The common earthworm is naturally dealt with very fully. Tunicates are next considered and then echinoderms. Here, again, justice is done to the work of Preyer and Romanes. The number of illustrations (17) appears to us rather small for such a mass of text.

Our general appreciation of the work appears abundantly from what has been said.

---

*Hook-worm Disease: Etiology, Pathology, Diagnosis, Prognosis, Prophylaxis, and Treatment.* By GEORGE DOCK, A.M., M.D., Professor of Medicine; and CHARLES C. BASS, M.D., Instructor of Clinical Microscopy, Tulane University of Louisiana, Medical Department. London: George Keener and Co. 1910. Pp. 250. Price 9s. net.

THE authors of this work rightly say that few diseases surpass uncinariasis in the strangeness of its history, the importance of its ravages, or the theoretic ease of its extinction. Its study in America has shown the heavy load which it can lay upon a country. Largely due to it, a region which should be most fertile lies relatively uncultivated; a population derived from the best colonising blood

ekes out a miserable existence, and is doomed to extinction unless it is soon relieved of the infection.

The affection is in truth widespread, as evidenced by its synonyms expressive of the various countries in which it has been found. The introductory chapter deals with its history, from which we learn it was known as early as the seventeenth century. It occurs in tropical, subtropical, and temperate climates, having been met with from latitude 51° N. to nearly 40° S.; in the tropics it is, quite probably, the chief cause of the so-called tropical anæmia. The chief factors in the existence of hook-worm infection are high temperature and moisture; thus, in the mines of Westphalia the higher the temperature, the greater the percentage of infection, whilst the influence of moisture has been noticed by all who have studied the disease. The authors give a very good and lucid description of the zoological features of the *ankylostoma duodenale* and of the *necator Americanus*. They then pass on to the modes of infection, which are through the mouth directly and through the mouth indirectly by way of the skin, the former being of minor importance, as skin infection is practically the only source of the disease. The reproductive stage of the parasite is reached only in the intestinal canal, where it lays its eggs, which pass out with the fæces, not hatching in the canal on account of lack of oxygen. How enormous is the number of eggs passed with each stool has been shown by Leichtenstern, who estimated the total daily excreted in one of his cases to be over 4,000,000. The requirements for hatching are detailed, amongst which are moisture, shade, and warm temperature. The infection may occur then through the drinking water and food; but the chief important route is through the skin, as shown by Looss in 1898.

The pathological anatomy is well described; in this chapter the question of the causation of the anæmia is considered. This is due in many cases to the loss of blood caused by the sucking of the mucous membrane by the parasites and the subsequent hæmorrhage; but this is not the cause in many other instances, the anæmia here being due to the poisonous products absorbed from the foci of inflammation caused by the parasite in the intestine. The authors then pass on to the symptomatology of hook-worm disease; this chapter is illustrated by some excellent figures. The changes in the blood, the joint pains, the affection of the skin, the symptoms in the respiratory, circulatory, digestive, and genito-urinary systems are all detailed in a lucid manner, as are those of the eyes and nervous system. Then we come to the section concerning the diagnosis, which treats of the examination of the fæces, the description of the eggs and their differentiation from other ova, and the special methods for greater certainty in finding the eggs. Next, in the chapter on prognosis, the mortality is considered, and the effect of intercurrent diseases and complications. The work concludes with the methods of treatment.

As regards prophylaxis, the essential elements are the stopping the danger of infection by exterminating the mature worms in the bodies of human beings, the preventing the growth and existence of larvæ in the places where they develop, and the prevention of infection by larvæ. In considering the treatment of the hook-worm in the intestine the best way of administering thymol is entered into, and the symptoms of intoxication by this drug and their counteraction are detailed. Amongst other drugs that have been recommended are beta naphthol, oleoresin of male fern, eucalyptus oil, podophyllin, kerosene oil, and guaiacol carbonate, whilst stress is laid on the importance of the general treatment of the anæmia induced by this disease.

This treatise on hook-worm disease is the most comprehensive account of the affection that has yet been published, and we congratulate the authors upon a valuable piece of work.

---

*Argentina: Past and Present.* By W. H. KOEBEL. Illustrated. London: Kegan Paul, Trench, Trübner, and Co., Limited. 1910. Pp. 455. Price 12*s.* 6*d.* net.

As a boundless field wherein the great synthetic processes producing man's vegetable and animal food are peculiarly favoured, the Argentine may well deserve the attention of the medical profession. There is not the least doubt that Argentina is going to be one of the most prolific producers of the meat and wheat supply of the world. Already the exportation of these foods to this country has reached a very large scale, and the time when fodder and cereals can no longer be grown in the Argentine under the present highly economical conditions must be very far distant. This fact connotes a country of vast plains of grass and well-watered areas, and the traveller who expects to find in the Argentine a physiographically interesting country will be deeply disappointed. It is an ocean of grass with its levels as unrelieved as the sea itself. It rejoices, however, in uninterrupted sunshine for the most part of the year, and the air is peculiarly exhilarating, being apparently endowed with an aseptic property which gives it a healthy and healing power. "Qué buenos aires son los de este suelo!" (What fine air there is in this country!) is said to have been the exclamation by the first man who stepped ashore at the mouth of the River Plate. Occasionally the country is visited with serious droughts, but on the whole it is more fortunate in this respect than many other pastoral countries. There is no record of a rainless spell, at all events, which has ended in total calamity, and although the quite recent visitation was severe it has at length broken up. Another enemy to be dealt with is the locust whose ravages every year increase in severity. Mr. Koebel has written a very interesting account of this country which, with the successful applications of science, has such a future before it. He has followed tracks with which the reviewer is familiar, who has found therefore peculiar pleasure in reading the details of the narrative, which are accurate and picturesquely set out. The history and ethnology of the people are not the least interesting part of the book; there are some charming stories of the peones, estancieros, the gauchos, and so forth, and the account of the great industrial developments which threaten to reach colossal dimensions is full of interest. "The Story of the Pastures" has given us particular pleasure in reading. Equally well described are the doings in the camps. The book will appeal not only to the reader who may anticipate a visit to the Argentine or who may happen to have been there, but to the reader who takes a general interest in the development of new countries.

---

*Andreas Vesalius: The Reformer of Anatomy.* By JAMES MOORES BALL, M.D. Saint Louis: Medical Science Press. 1910. Pp. 149. Price $5.

THIS is a book that will delight the heart of the bibliophile as well as the eye of the artist and the soul of the medical antiquary. Basing his work on Roth's "Andreas Vesalius Bruxellensis," Berlin, 1892, Dr. Moores Ball, a medical antiquary of zeal tempered with discrimination, has produced a volume rich with the fruits of personal research. The setting is worthy of the contents. It is printed on heavy tinted Normandy vellum that shows up the type and the engravings admirably. There are upwards of 50 illustrations, reproduced from the original publications of Vesalius or from the works of preceding anatomists. The frontispiece is a sepia-tinted photogravure of Vesalius, and there is also a reproduction from an ancient copper-plate portrait of him.

The scope of the book is wide. It begins with an

introduction to the history of medicine, particularly dwelling on the period of the Renaissance. After briefly tracing the study of anatomy from Egypt and Greece to the time of Frederick II., Dr. Ball devotes a chapter to Mondino and his "Anathomia," first printed at Pavia in 1478, and another chapter to the successors of Mondino, of lesser fame, of whom, perhaps, Berengarius is the most widely known. Then we are introduced to the early life of Vesalius, who was born in Brussels on Dec. 31st, 1514, of a family in which medical learning was traditional; for his great-great-grandfather Peter, his great-grandfather John, his grandfather Eberhard, and his father Andreas, were all accomplished in the field of letters and in medicine. But in addition to the influence of paternal heredity his mother's fostering care also undoubtedly exercised considerable influence in the formation of his career, as is so often the case with great men. Dr. Ball follows in successive chapters the career of Vesalius at Louvain, his studies in Paris and Venice, his graduation at Padua in December, 1637, and his work there as the occupant of the first purely anatomical chair ever instituted. In the next chapters the literary labours of Vesalius are closely followed, his "Tabulæ Anatomicæ," the "De Humani Corporis Fabrica" (his greatest work), and the Epitome thereof. The contents of the "Fabrica" are reviewed in some detail, and the conclusion is formulated that although this great work contains many errors that a tyro of the present day would laugh at, it laid the foundations of our knowledge. Vesalius overthrew the idol of authority in anatomy and taught us to look at Nature with our own eyes. Two chapters follow respectively on the Contemporary Anatomists of Vesalius and on his Commentators and Plagiarists; while the book closes with an account of his abandonment of the scientific career in disgust at the jealous opposition he experienced, particularly at the hands of his former pupil and friend, Columbus Realdus; of his career as archiatros to the Emperor Charles V. of Spain; of his pilgrimage to Jerusalem, and his shipwreck and death.

Dr. Ball has given us more than a mere account of Vesalius: it is a scholarly *résumé* of the history of medicine of the period. A glance at the copious index will show how many personages, great and small, appear in the course of the book, and of these quite a number receive a biographical sketch of their own.

---

*Logic for the Million.* Edited by T. SHARPER KNOWLSON. London: T. Werner Laurie. 1911. Pp. 248. Price 6*s.* net.

WITH all due respect to the great Herbert Spencer—whom the author of the present book, in his introduction thereto, quotes as having expressed himself in the following terms: "I have at no time paid the least attention to formal logic, and hold for all practical purposes it is useless"—a capacity to reason correctly is at the bottom of man's successful evolution above his fellow animals. But for this faculty being to some extent inherent, man could never have survived in the earliest ages against other animals better equipped than he for the struggle with Nature. The displacement of logic from the educational curriculum is in part due to the irksomeness of the cut-and-dried methods of the schools, and in part to the fashion of referring all reasoning to the arbitrament of "common sense." Now, common sense acts well enough in reasoning when the value of all the terms is known, but when a term of the attributes of which we are ignorant comes into play "common sense" becomes powerless to keep a check upon the result of our reasoning, the correctness of which must consequently depend on our capacity to test the validity of our statement of the relations between given propositions, as we test the validity of our arithmetical or algebraical propositions, by abstract rules. To all scientists, therefore, among whom in some degree must be classed all medical men, a knowledge of the principles of logic is as necessary as a knowledge of arithmetic to accountants. Logic has been belittled as a musty mediæval study—a conclusion based on reasoning that is itself incorrect; for this belittling has its basis mainly on the exploitation of sleight-of-mind tricks in the disputations of the schools, so that the attribute of a part or aspect has been unwarrantably ascribed to the whole. Thus the arguments adduced to show the uselessness of the study of logic really demonstrate the necessity for it.

The author aims to bring the science of reasoning out of the atmosphere of the class-room into the arena of daily life by using as illustrations of logical principles arguments from old and new writers and from the political and social discussions of the age, and by devoting attention to concrete cases, reviewing them in the light of facts as we know them instead of confining himself to the formal relations of series of abstract propositions. He is at his best, perhaps, when he illustrates the various ways in which, in ordinary parlance, we are accustomed to express ideas and to form judgments, such as constitute the subject, in most treatises on formal logic, of the various modes of syllogistic argument, and when he translates the formal syllogistic rules into self-explanatory propositions in the language of the "man in the street." Mr. Knowlson is to be commended for this new edition, very largely rewritten, of an old book. We think, however, that some injustice is done to the author of the original book, Mr. J. W. Gilbart, F.R.S., whose fourth edition of "Logic for the Million," dated 1854, lies before us; for we cannot consider that his authorship is even suggested, not to say acknowledged, by the statement on the title-page that the book is "edited" by T. Sharper Knowlson, or by the brief mention in the preface wherein Mr. Knowlson tells us what he, "following the lead of J. W. Gilbart F.R.S.," has endeavoured to do.

## LIBRARY TABLE.

*Darwin and the Humanities.* (The Ethical Library.) By JAMES MARK BALDWIN, D.Sc., LL.D., Foreign Correspondent of the Institute of France. Second edition. London: Swan Sonnenschein and Co., Limited. 1910. Pp. 125. Price 3*s.*—The vital and transforming influence of the Darwinian theory of natural selection—which the author thinks might with entire appropriateness be called "Wallaceism"—on the biological sciences, as well as its influence on the spirit and methods of scientific inquiry generally, is well known and admitted. The corresponding influence of Darwin and the growth of Darwinism in the sciences of the Humanities has been but scantily traced out and recorded. In this booklet—which had its origin in a paper by the author on "The Influence of Darwin on the Mental and Moral Sciences"—the author proceeds to give a terse account of the influence of Darwinism on psychology, ethics, and sociology, and on the more general topics of logic, scientific method, philosophy, and religion. The author expresses the view that possibly the work may be found clearer and more effective from its brief and succinct mode of presentation. It is just possible that to the average reader the presentation is too "succinct." As an example of the succinct we may quote the author's reply to the question, What is natural selection? Simply the fact that "*some creatures survive and propagate their kind when others of the same kind cannot. That is all.*" To illustrate how so simple a fact can be of such consequence that the mere recognition of it amounts to a theory of evolution and establishes a great principle in science, the author

deals shortly with (1) over-production with variation; (2) struggle for existence; (3) survival of the fittest (H. Spencer's phrase); and (4) inheritance of inborn characters. He then proceeds to measure the influence of Darwin in psychology, and he begins with the vexed question of the rise of the animal instincts. Leaving aside the account of Weismann's view on "intra-selection," he boldly deals with plasticity and mind, and the progress made by the brain in mammals—the organ of increasing plasticity and educability. Its evolution is correlated with the decline of the instinctive and completely congenital functions. Next he deals with the utility of mind or the intelligent type of function, and then discusses heredity, physical and social, and the importance of gregariousness, play, and imitation. He thinks that Huxley failed to grasp how morality could be explained on Darwinian principles, for according to Huxley in our moral sense we have a principle of altruism and a rule of conduct that directly contravenes the principle of "struggle for existence." On the contrary, according to our author, "Morality has arisen because it is socially useful; that is the Darwinian account." The other chapters deal with logic, philosophy, and religion. The author makes out a strong case for his contention. It is a work which requires accurate thinking and keen logical acumen to grasp at the first reading, especially to those not well versed in modern problems of Darwinism and Philosophy. The work is dedicated to Alfred Russel Wallace, whose interest extends to all the Humanities.

*Forbidden Fruit for Young Men.* By Lieutenant-Colonel SETON CHURCHILL. Eighth edition. London: James Nisbet and Co., Limited. Pp. 269.—A book which has reached its eighth edition speaks for itself, and we can say in addition that the difficult subject with which Colonel Seton Churchill deals is treated with dignity, plain speaking, and the necessary reticence. Ignorance combined with natural curiosity is perhaps the most powerful stimulus to sexual licence and the evils which flow therefrom. This book gives the necessary instruction in a manly and simple fashion, and we can imagine no book from which a father might instruct his child better as regards the all-important [illegible] matters with which it deals.

*The Valley of Achor.* By Mrs. PHILIP CHAMPION DE CRESPIGNY. London: Mills and Boon, Limited. Pp. 331. Price 6*s*.—To any reader who likes an exciting story and who does not mind obvious absurdities we recommend this book. One of the protagonists, young, clean shaven, and a Fellow of the Royal Society, is a student of infectious disease peculiar to the tropics, and has come to the conclusion that the germs of probably all tropical diseases have intermediary hosts for development before arriving at maturity. Mrs. De Crespigny here reminds her readers that the "tsetse fly and mosquito as intermediary hosts in the case of creeping (*sic*) sickness and yellow fever were already well known to science." The other protagonist is wrecked in the Bay of Biscay and is picked up by a passing fishing vessel, a "little schooner," which eventually landed him at La Guayra, which we find to be a port on the north coast of Venezuela. From here to the Bay of Biscay is a long way for a little fishing schooner to go. Accompanied by his servant, who had also been picked up, the wrecked man then explores the basin of the Amazon and is rewarded by the discovery of a white nation. He comes home, is fêted so much so that we are told that it is nearly certain that Oxford will make him an LL.D.! Then a rumour gets about that he has never been in South America at all, but his character is triumphantly cleared by the other protagonist, who demonstrates a parasite in his blood (Hepatozoon perniciosum) which had only been found hitherto in rats and mites in South America. Despite its absurdities, the story is quite a good one.

## JOURNALS AND MAGAZINES.

### NEW MEDICAL JOURNALS.

*The North of England Clinical Journal*, the organ of the Newcastle-upon-Tyne Clinical Society. Vol. I., No. 1, Jan., 1911. Newcastle-on-Tyne: 24, Eldon-square. Price 1*s*.

*The Canadian Medical Association Journal.* Vol. I., No. 1, January, 1911. Toronto: Morang and Co., Limited. Price $5 a year; single copies, 50 cents.

*Aesculape.* Revue Mensuelle Illustrée, Médecine, Chirurgie, Pharmacie, Science, Lettres, Arts, dans leurs rapports avec la Médecine. Vol. I., No. 1, January, 1911. Paris: A. Rouzaud. Price 1.50 francs (abroad 2 francs). Subscriptions yearly 20 francs (abroad 25 francs).

*Répertoire de Médecine Internationale.* Revue et Revue des Revues. Vol. I., No. 1, January, 1911. Paris: Jules Rousset. Price 10 francs (abroad 14 francs) yearly; single copies, 1 franc.

Four new medical journals have this year made their appearance on our table, two in English and two in French. *The North of England Clinical Journal* is the organ of the Newcastle-upon-Tyne Clinical Society. It is to be issued quarterly under the editorship of Mr. George Foggin, aided by an editorial committee. It contains an address on the Menopause, by Sir J. Halliday Croom; the presidential address of Dr. E. Napier Burnett on Obstetrics in Relationship to some of the Allied Sciences; an illustrated article on the Pathology of Lymphadenoma, by Dr. Stuart McDonald; and papers on the Treatment of Certain Skin Diseases by Carbonic Acid Snow, by Dr. D. Wells Patterson; a record of the Year's Progress in Public Health, by Dr. Harold Kerr; the inevitable Ehrlich-Hata "606," by Dr. Herbert J. Slade; A Case of Actinomycosis, by Dr. T. M. Allison; and Some Notes on Clinical Cases and Pathological Specimens. This first issue gives promise that it will perform a useful function.

Our Canadian brethren are also putting out a very [illegible]able journal, *The Canadian Medical Association Journal*, published in Toronto, under the editor[illegible]ship of Dr. Andrew Macphail. It contains seven [illegible]ginal articles (one, of course, on "606"), including the opening address of the Medical Faculty at the University of Liverpool, by Professor Macallum of Toronto, and an interesting paper by Dr. James R. Goodall and Dr. L. C. Conn, in which they lay stress on the coincidence noted repeatedly by the former of the concurrence of lipomata with malignant disease of the thyroid, and suggest a causal relation between them. We feel strongly in sympathy with the writer of the editorial article on style in medical writing.

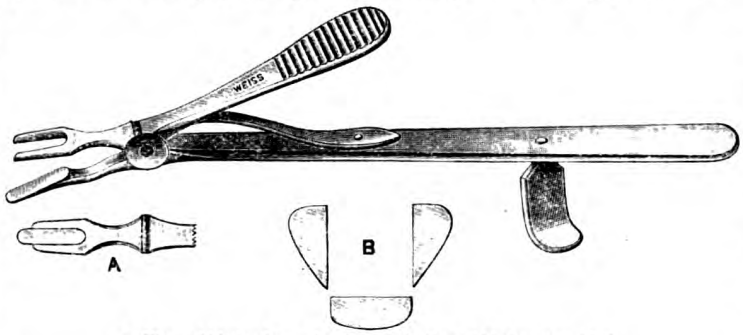
*Aesculape* is a monthly illustrated magazine of medicine, surgery, and pharmacy, published in Paris. It aims to claim proper recognition for the work of the Græco-Latin peoples in Europe and America, which apparently, in its opinion, does not receive an adequate share of credit. It contains many well-illustrated articles of interest, some of them, as for instance that on the "*Survie de la pensée chez les décapités*," having an antiquarian flavour. "606," of course, is the "*question du jour*."

Finally, the *Répertoire de Médecine Internationale* strikes out a novel line for itself. It is divided into three parts, the first of which contains original articles, the last is devoted to professional matters and bibliography, while the intermediate portion consists of at least 60 pages of "loose leaf" abstracts from the medical journals of the world, grouped into 28 classes by subjects, so that they can be filed away after the fashion of the well-known vertical filing system, to form a constantly expanding text-book of medical progress. Section XII., Venereal Diseases, is, of course, largely occupied with "606." The editor is Dr. F. Louis Hahn, chief bibliothécaire of the Paris Faculty of Medicine. We should like these abstract tablets better if the one-third space at the bottom were left vacant for notes in place of being allotted to advertisements.

# New Inventions.

## TWIN SCISSORS FOR SCLEROTOMY (HERBERT'S OPERATION).

THE instrument shown in the figure is designed to facilitate the performance of Herbert's operation of sclerotomy for the relief of chronic glaucoma. The idea in view has been to reduce the difficulty and time involved in making the two lateral cuts for the valve-like scleral flap which is the feature of this valuable operation. The instrument has been modelled upon the plan and does the work of two pairs of scissors, so that it has been called "twin scissors." It makes, on the gradual and shearing approximation of its blades, two parallel cuts, each 4 mm. in length, and separated from each other by 3 mm. In appearance it is something like a needle-holder, but the blades are different. The lower or male blade is flat and bevelled, so that each side presents a sharp edge; its free end is rounded and blunt and projects 2 mm. beyond the female blades. The upper or female blades are a pair of parallel sharply bevelled blades springing from a common stump. When the handles of the scissors are closed the female blades shear down on the sides of the male blade and come to rest, overlapping it (A). The instrument shown has been used for operating on four human eyes with successful results; it was then used to cut sheep's eyes, rubber sheeting, cloth, and paper until the keenness of the blades was dulled, then it was successfully sharpened.



A. View of blades from above. B. Section of blades magnified.

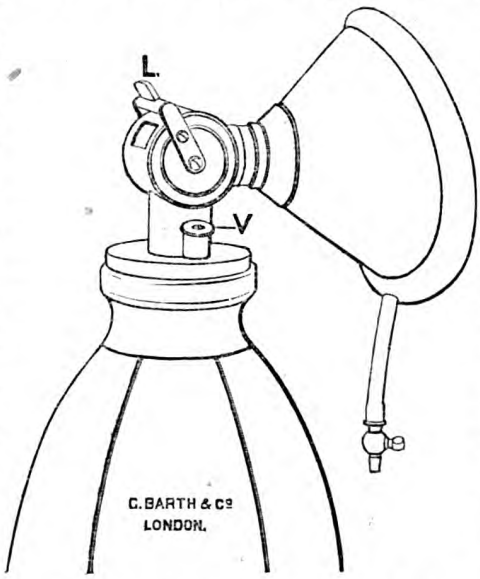
The lower handle of the instrument has a novelty in the provision of a finger plate, which, being slipped between the second and ring fingers at the joint of the end phalanges, gives a very steady and easy grip of the scissors. In cutting with the scissors it is essential to press the handles together evenly; if a lateral thrust be imparted to them the necessary fractional play of the hinge will allow one or other of the female blades to engage its side of the male blade too firmly and perhaps check the cut; if the lower handle of the twin scissors be operated by the ends of the fingers, just as in using ordinary scissors, the cutting will be easy and even. Trial cuts with the scissors should be made on rubber sheeting, but not on paper or card. In operating with the instrument I have found it convenient to first turn forward a flap of conjunctiva from the chosen site of the sclerotomy; then the keratome is inserted into the sclerotic 4 mm. from the clear corneal margin and passed through and under the sclerotic until its point appears within the corneo-iridic angle; it is pushed on until a clear 3 mm. of the blade is within the anterior chamber; the keratome is then withdrawn. Now the male blade of the twin scissors is pushed along the track of the wound until the projecting 2 mm. of the blades shows within the anterior chamber, the scissors are then closed, the cuts made, the male blade gently withdrawn, and with the replacement of the conjunctival flap the operation is complete. In the four eyes operated with this instrument eserine was used subsequently for three days.

The twin scissors are made by Messrs. John Weiss and Son of London.

N. BISHOP HARMAN, F.R.C.S. Eng.
Harley-street, W.

## AN IMPROVED ETHYL CHLORIDE INHALER.

HAVING been required lately to administer ethyl chloride to children in considerable numbers I could not help being struck with the difficulty of "filling" the bag—i.e., of getting sufficient air into it to dilute the ethyl chloride vapour to the required degree, and to allow the patient as the breathing deepened with narcosis to take a full breath without entirely emptying the bag, and so getting the full dose of the anæsthetic in one inspiration—a really dangerous occurrence. I therefore devised a two-way cock to be placed between the face-piece and the bag, by means of which the first few breaths of the patient can be turned into the bag until it is sufficiently filled, and then, by drawing a lever, L, up towards the face-piece, the valve can be cut out and re-breathing permitted. In this way, too, the first breath or so which the patient takes after the face-piece has been applied is of air—a factor of some importance in restoring the confidence of very nervous patients and so conducing to a better anæsthesia. The ethyl chloride is sprayed directly into the bag, and in order that this may be done easily I have had a small valve, V, placed on the collar which supports the bag. This valve opens when the nozzle of the ethyl chloride tube is pressed against it, and closes automatically immediately the nozzle is withdrawn, a tube below carrying the discharge well away from the face-piece. The ethyl chloride may be sprayed into the bag either before it is applied to the patient's face, the valve practically preventing any escape until it is turned into the position for re-breathing, or it may be sprayed in while the patient is filling the bag, or added in divided doses as narcosis deepens—the method which I prefer. The apparatus has been made for me by Messrs. Barth and Co., and I have now given it a trial in over 100 cases (20 adults, with only one case of retching afterwards, and 90 children, with three cases of retching, two having to be detained about three-quarters of an hour owing to their feeling "faint and sick"). In no case was there any difficulty or hitch during the induction, the operation, or the recovery of consciousness.



C. J. LOOSELY, M.R.C.S. Eng., L.R.C.P. Lond.,

# THE LANCET.

*LONDON: SATURDAY, MARCH 4, 1911.*

## The Immunity Reaction in Diagnosis.

THE study of the various aspects of the complex responses on the part of animal organisms to bacterial and other infections, which are collectively classed as immunity reactions, is constantly enriching practical medicine with new and valuable methods of diagnosis and with specific forms of treatment. In regard to diagnosis alone a vast amount of laborious experimental work has been carried out during the past few years, and as a result numerous methods have been tentatively introduced to be replaced by more accurate and more specific tests as our knowledge has advanced. Some of these immunity reactions, such as the agglutination phenomenon, of which WIDAL'S well-known test is the type, and the Bordet-Gengou reaction, depending upon the deviation of complement by the combination of an antigen and its specific antibody, are of very general applicability and have become established as more or less routine diagnostic procedures. Other methods are more complex or less easily carried out, and are as yet largely restricted to scientific laboratory investigations. An interesting, intelligible, and useful account of these applications of the processes comprised under the term "immunity" has been given by Dr. W. D'ESTE EMERY in the Hunterian lectures delivered before the Royal College of Surgeons of England on Feb. 6th and 8th and published in THE LANCET of Feb. 25th and in our present issue. Dr. EMERY discussed briefly the general mechanisms of hypersensitiveness and immunity, and then illustrated the application of the general principles by detailed reference to the newer methods of diagnosis of tuberculosis and syphilis. The value of his review of this important subject is greatly increased by the practical and utilitarian standpoint from which he has approached it, and also by the record of his own personal experience with the ordinary methods and with special modifications devised and introduced by himself. Dr. EMERY pointed out the important fact which recent researches have established, that the response to an infective agent comprises, not only processes tending to increase the protective or defensive agencies, but also others tending to render the body more susceptible or sensitive to the infective agent or its products. This increased susceptibility or anaphylaxis, the most familiar instance of which is the "serum disease" which sometimes occurs after injections of antitoxic sera for diphtheria, it now appears is an essential feature in the bodily response to infection and to invasion of the tissue fluids by alien proteins or antigens. It forms the basis of the tuberculin and mallein reactions, since it is only after sensitisation to these substances by previous injection or by a pre-existent lesion that the specific reactions occur. It is therefore important to recognise that this hypersusceptibility or anaphylaxis is as much specific as the more obvious and protective immunity. The exact relations existing between the two processes are as yet obscure, but, as Dr. EMERY pointed out, they may coexist, and a clear and unequivocal demonstration of either of them is definite proof of an infection, present or past.

In regard to tuberculosis, the application of these fundamental processes to diagnosis is a difficult one, at any rate in adults, partly owing to the nature of the tubercle bacillus, which is less easy to work with than many other organisms, but more particularly owing to the fact, now so generally recognised, that the great majority of adults have been exposed to infection and have acquired some degree of immunity to this organism. Dr. EMERY suggests that almost everybody is constantly being unsuspectedly vaccinated against the tubercle bacillus through the alimentary canal and the respiratory organs. Although we need not necessarily subscribe to this dictum, it is none the less certain that many forms of the tuberculin reaction, such as VON PIRQUET'S cuti-reaction, which may be useful in young children, are practically valueless in adults, owing to the fact that they are given by a large proportion of apparently normal persons owing to the partial immunity they have acquired. What is wanted for practical purposes is a reaction which shall demonstrate the presence of a specific lesion and its activity. Dr. EMERY went on to study the various methods which have been introduced for diagnostic purposes, depending upon the presence of specific antibodies in the serum—that is, upon a qualitative and quantitative study of the more definitely protective substances formed in response to infection—viz., antitoxins, precipitins, agglutinins, cytolysins, and opsonins, although he confessed to some hesitation in including the last-named substances among the antibodies, but only for technical reasons which do not affect their practical utility. Tests based upon the development of an antitoxin for tuberculous toxin, or of a precipitin for the protoplasm of tubercle bacilli, are rather of theoretical interest than of practical value, while little, if anything, is known of a bacteriolysin for this organism. The agglutinin reaction has, however, been used by various observers, but the difficulties encountered are such as to prevent its general application; moreover, the results obtained are not sufficiently characteristic to be of great diagnostic value, since, as Dr. EMERY stated, a case may progress from start to finish without showing the presence of agglutinin in the blood. The value of the opsonic index in diagnosis has been much debated, and it is now generally admitted that a single determination is only of value if it fall considerably outside the somewhat wide normal limits allowed for this index. A comparison of the results before and after exercise, massage of a local lesion, or injection of tuberculin is of much more value if the technique can be relied on. Certain methods have been introduced having as their object the estimation of the total antibodies. The first of these is the so-called meiostagmin reaction, which depends upon the lowering of surface tension occurring when an antibody and its corresponding antigen have been incubated together for two hours. The other method is the well-known Bordet-Gengou

reaction, depending upon deviation of complement by an antigen and amboceptor combination, red corpuscles specially sensitised by the addition of a specific hæmolytic amboceptor being used as the indicator. Reactions obtained by this method have given somewhat variable results, and Dr. EMERY maintained that since these antibodies for tubercle bacilli may be present in apparently healthy persons any method of studying them to be of use practically must be a quantitative one. He claimed to have discovered a comparatively simple modification of the Bordet-Gengou reaction for this purpose. He found that the absorption of complement in this reaction is on the average much shorter with serums from tuberculous patients than with those from normal persons. His method, therefore, consists in the determination of the "absorption time" of complement by these serums in the presence of the antigen, which is a standard emulsion of tubercle bacilli. The indicator is the usual emulsion of sensitised red blood corpuscles, and the absence of hæmolysis is the index of absorption of the complement. The technical details were fully described by Dr. EMERY and can be studied in his lecture. It is with the results obtained that we are more particularly concerned. In 34 cases of diseases other than tuberculosis and of healthy persons the average absorption time was 18·1 minutes, the maximum being 35 and the minimum 2·5. In tuberculous patients the absorption time was as a rule greatly diminished, the average being 7·4 minutes. Absorption times of less than 2·5 minutes were obtained in 25 out of 56 tuberculous serums examined. If this time be regarded as the criterion the test was obtained in 44·6 per cent. of tuberculous and in 8·8 per cent. of non-tuberculous. It is obvious, therefore, that this test is not absolute; moreover, tuberculous cases do not always give a shortened absorption time, and may indeed give a lengthened one, more particularly in the negative phase after inoculation with tuberculin. Some observations made upon this negative phase seemed to indicate that it was not due to, or at any rate not entirely due to, a diminution in the amount of antibodies in the blood, but more probably to a substance inhibiting the union of the antigen, amboceptor, and complement. Dr. EMERY'S method has therefore already proved of value, and we may endorse the plea which he urges for more careful investigation of the presence of antibodies in the blood in tuberculous diseases and of their quantities as likely to afford help in diagnosis, prognosis, and treatment. The bacteriological diagnosis of this disease is still far from satisfactory, and in view of the great importance of early recognition of cases of tuberculous disease we welcome any researches tending to further this aim.

The second of these lectures was devoted to a consideration of the nature of the Wassermann reaction, with a description of a simple quantitative modification already published by Dr. EMERY in THE LANCET.[1] The original Wassermann reaction is a special application of the general Bordet-Gengou phenomenon, and was indeed one of its early applications to diagnosis. It is, however, of interest to notice that recent work has demonstrated that the substance in the serum of syphilitic patients which gives the reaction is not a true antibody, and is, moreover, not specific, since it occurs in other diseases and in normal serums. The characteristic feature of the substance in syphilis is its presence in excess; hence the great importance of a quantitative method of applying the test. The explanation of the Wassermann reaction must necessarily be different from the ordinary instances of the Bordet-Gengou phenomenon where a specific antibody and antigen are concerned, and with this and other theoretical considerations Dr. EMERY dealt at some length. Into the details of his own method it is not necessary to enter; the advantages claimed for it are its simplicity and the ease with which it can be applied quantitatively. He concluded with some useful information regarding the results of the test and its diagnostic and prognostic indications. In the early part of the primary stage a negative result is of no value, but a positive reaction may be expected if the supposed chancre has been present for six weeks or more. Children and adults with hereditary syphilis as a rule give very strong reactions. In the later stages of the disease it may be stated that if the reaction is present the patient is not cured and a continuation of treatment is advisable. If there is no reaction it is more difficult to decide, since cases are stated to occur in which no reaction is obtainable at any time; but if a reaction has been present at one time, and it is subsequently found to be absent, the probability of cure is great, but it must be remembered that mercury itself inhibits the reaction, so that a negative reaction while the patient is under mercurial treatment is not to be taken as evidence of cure. Dr. EMERY'S lectures are an interesting practical contribution to our knowledge of an important subject and will repay careful perusal.

[1] THE LANCET, Sept. 3rd, 1910, p. 732.

## Psychological Medicine and Social Problems.

MEDICAL pluralism is an institution which finds a good many critics nowadays, but even those who are loudest in its dispraise will admit that it may sometimes have compensatory advantages when it affords to a competent observer an opportunity of seeing at once several different aspects of a complex and many-sided problem. How much such an opportunity, wisely used, may contribute to clarifying and defining our views on a question of great present importance is strikingly shown in a very interesting volume recently published by Dr. HELENEFRIEDERIKE STELZNER under the title of "Die Psychopathischen Konstitutionen und ihre Sociologische Bedeutung" (Berlin, KARGER, 1911). Fräulein STELZNER is a pupil of Professor ZIEHEN, and she adopts that alienist's well-known views regarding the characteristics and position of those cases of mental abnormality which he includes under the title of "Psychopathische Konstitutionen," a group of not very clearly defined limits which corresponds perhaps most nearly in our phraseology to the "borderland cases" so inimitably described by MAUDSLEY. Individuals belonging to this class, by reason of their incapacity for social adaptation, come into conflict with their environment at many different points, and so form an element, and a very disturbing element, in

many different bio-social problems. As varying circumstance determines, they will appear at one time as criminals, at another as lunatics, or, again, as inebriates or vagrants or prostitutes; and the observer who sees them in one and only one of these phases is naturally disposed to exaggerate their tendency to the particular form of anti-social activity which comes into his sphere of observation.

It is the good fortune of Fräulein STELZNER that she is able to take a more comprehensive view, for in addition to her opportunities of studying this morbid temperament in Professor ZIEHEN'S psychiatric clinic at the Charité and in his polyclinic, she can draw on her experience as physician to a reformatory for girls, as school doctor, and as alienist expert to the court for juvenile offenders at Berlin. Her opinions, therefore, are the outcome of an exceptionally wide survey of the question which she discusses; and as many details of that question are engaging attention in this country at present we may learn some useful lessons from her experience. The main conclusion emphasised in her work is that the prevalence of the psychopathic diathesis is very much wider and its importance from a sociological point of view very much greater than it has been customary to assume. As becomes a pupil of Professor ZIEHEN, Fräulein STELZNER lays much stress on the exact determination of intellectual capacity, relying for this purpose on the methods devised by Professor ZIEHEN and described by him in his "Prinzipien und Methoden der Intelligenzprüfung" (Berlin, 1908). And she maintains that the failure to apply such tests systematically to children who appear backward at school leads to the inclusion of morally deficient and abnormal children in classes for the mentally defective, with results which are fraught with evil both for the borderland cases, which do not receive the appropriate guidance and control that they need, and for the intellectually feeble, who are dominated and corrupted by the quick-witted but unstable and frequently perverse children of the psychopathic group. Instances are, of course, not uncommon where psychopathic symptoms are met with in children who are also intellectually defective, but it appears to be Fräulein STELZNER'S experience that in such cases the intellectual weakness, if at all pronounced, is the practically important factor, so that children of this sort do not need to be segregated from the rest of the weak-minded. Such segregation, on the other hand, is imperatively necessary in the case of the psychopathic children, whose abnormality is shown mainly in the sphere of feeling and impulse. And it is equally important to separate such children from the normal but undisciplined children who, as juvenile offenders, truants, and so forth, form the ordinary population of reformatory schools. The system enforced in these institutions, designed as it is for individuals of normal disposition, is wholly unsuited for the morbid temper of the psychopathic child; not only does it fail to provide the special influences for developing such aptitudes for good as he may possess, but it provokes and stimulates his anti-social tendencies by the restraints of a rigid discipline. The reformatory constitutes, therefore, a peculiarly unfavourable *milieu* for children of this class, and Fräulein STELZNER maintains that such degenerates form a very large proportion of the incorrigibles who, in Germany as in this country, are quoted as evidence of the failure of the reformatory system. What they really show, as the authoress rightly insists, is the absolute necessity of a skilled psychiatric scrutiny of the children whom it is proposed to treat by these reformatory methods.

It would appear that the unwillingness to recognise the rôle of the psychologist in matters of reformatory education is not confined to Great Britain, though the reactionary tendency may not perhaps be shown in quite such an aggravated form in other countries as it is with us. The very fact, indeed, that a trained alienist like Fräulein STELZNER is attached as expert to the juvenile court of Berlin suggests a very instructive comparison with the attitude of our legislators, who, when they recently established juvenile courts by the Children Act of 1908, never, of course, entertained the idea that the mental condition of the youthful offender ought to be taken into account in determining the best method of treating him. Meanwhile, it is interesting to note that the experience gained in countries where it is considered worth while to make this question a matter of skilled investigation has found out, as Fräulein STELZNER tells us, one important reason why reformatories so frequently fail to reform. Fräulein STELZNER'S conviction on this point is, indeed, so strong that she does not hesitate to express the opinion that the whole elaborate and expensive machinery of juvenile courts, probationary supervision, rescue homes, and reformatories will prove very largely futile so long as no provision is made for the detection and segregation of these special types of mentally abnormal children. This is a view which ought to be carefully considered by the responsible authorities who will have to organise those larger schemes for the treatment of the feeble-minded and socially detrimental classes which are supposed to be contemplated in the legislation of the near future.

## Thomas *v.* Barker.

THE action of THOMAS *v.* BARKER, which occupied Mr. Justice DARLING and a special jury for three days of last week and resulted in a verdict for the plaintiff with 20 guineas damages, has brought to the most satisfactory of all possible tests the claim which has been brought forward, by or on behalf of the defendant, to be the discoverer of methods of manipulating diseased or injured joints which are unknown to members of the surgical profession, and to be able, by the employment of these methods, to effect cures in cases in which the best surgical skill has failed. Mr. H. A. BARKER has for nearly 20 years, we understand from Mr. W. T. STEAD'S pronouncements, carried on business as what is called a "bone-setter," and appears, like many other medically unqualified claimants to the possession of exceptional skill, to have enjoyed the confidence of a large *clientèle*. The comfortable position thus attained, however, was regarded as incommensurate with his merits by Mr. STEAD, a journalist who has from time to time achieved various kinds of notoriety by methods which many persons would have been content to leave unpursued, and who has been conspicuous, among other things, for a general and sympathetic admiration of several varieties of quackery. Mr.

STEAD, in the *Review of Reviews* for October, 1910, devoted eight double-column pages to a eulogium upon Mr. BARKER, in the course of which the public were informed that "in the last 19 years Mr. BARKER has treated by a careful manipulative surgery, without shedding of blood or use of drug, save that necessary for the production of temporary anæsthesia, more than 30,000 cases. These have been selected from a much greater number which have been brought to the great bone-setter for treatment. Of these 30,000 cases about 90 per cent. have been cured, and in almost every case the patient had patiently submitted himself to the best or the worst that the regular doctors could do for his benefit. To put it in round numbers, 27,000 incurable cases—that is to say, incurable according to the recognised methods of the recognised practitioner—have now been proved to be curable." Mr. STEAD'S declared object was to urge that Mr. BARKER'S methods should be reported upon by a committee of surgeons, how to be constituted he did not show.

There can be no doubt that the formation of such a committee, if it had been formed, would have been a very valuable method of bringing Mr. BARKER'S name before the public, while there was then, and still is, grave doubt whether the public is losing anything by the attitude of surgery towards bone-setting. We did not take Mr. STEAD very seriously in our reply to his attack upon ourselves in the course of his article on Mr. BARKER. With elementary manners he had referred to the *British Medical Journal* and ourselves under the respective names of GOG and MAGOG (although we can perceive no manifest reason why those distinguished civic characters should have been dragged into the controversy) and complimented us both with a shower of abuse. We contented ourselves with recalling to mind the completeness with which the nature of the manipulations of successful bone-setters, and the conditions in which these manipulations were useful, had been laid before the medical profession, in the first instance in our columns, by Dr. WHARTON HOOD, more than 40 years ago; and, while admitting that some unqualified bone-setters had been dexterous, and even frequently successful, we expressed a doubt whether Mr. BARKER'S supposed knowledge of anatomy, apparently gained without dissection, but by the perusal of two excellent manuals, could be sufficient to furnish him with safe guidance in his operations. Mr. STEAD was furious. He has discovered in THE LANCET a statement to the effect that manipulative surgery was a neglected corner of the surgical art, and, without mentioning that this was written over 40 years ago in relation to then existing conditions, he now attempts to use it as an admission which we are making to-day, and does so with our article of Oct. 22nd, 1910, staring him in the face and acknowledged by himself with splutterings of abuse in the *Review of Reviews* for November, 1910. Yet in a letter communicated as a sort of circular to the provincial press, and dated Feb. 14th, 1911, we find the statement that we have admitted that "manipulative surgery is a neglected corner of the domain of surgery." When we said this it was the truth; it is not the truth now, and to represent THE LANCET as believing it to be the truth now is a falsehood.

The case of THOMAS v. BARKER displayed Mr. BARKER as a member of a craft which has nothing recondite in its methods, and does nothing useful for which instruction may not be found in the writings of duly qualified practitioners. Mr. BARKER indeed has thrown important light upon his own limitations. A few days before the case of THOMAS v. BARKER came on for trial he wrote a letter to the *Times* in which he said that the vaguest knowledge of etiology or pathology would enable its possessor to distinguish between tuberculous arthritis and simple traumatic adhesions. We doubt whether Mr. BARKER could find a single surgeon who would agree with his dictum in this matter, or who would deny that the diagnosis in question is frequently one of extreme difficulty. We publish in another column a verbatim report of Mr. Justice DARLING'S summing-up in the recent case. Few things can be less satisfactory, from a scientific point of view, than a trial of this kind as it is usually conducted, because it is frequently the aim of counsel rather to obscure than to bring out the truth, and expert witnesses are often prevented from putting the matter before a jury in the most intelligible way. In spite of the difficulties hence arising, the case of Mr. THOMAS was tolerably plain, particularly as put to the jury by the judge. Mr. THOMAS sustained an injury to his knee ten years ago, from which it had never recovered, and before he went to Mr. BARKER it was the seat of tubercle. Notwithstanding its condition, Mr. BARKER caused gas to be administered to the patient and then moved the joint to an extent and in a manner which were matters of dispute. The same thing was done upon a second occasion. The patient appeared to suffer no immediate ill-effect, but soon afterwards became so ill that the surgeons who were then consulted decided upon an immediate amputation of the limb. The joint was totally disorganised, but the plaintiff eventually made a good recovery, and in due time brought his action for the injury which he alleged that he had sustained. It is quite clear that Mr. BARKER was wrong in meddling with a tuberculous joint, but the amount of his interference remains in doubt. Presumably this is why the plaintiff did not obtain larger damages. His 20 guineas will probably not go far towards his costs as between solicitor and client; and hence the case will afford little or no encouragement to the subjects of Mr. BARKER'S failures to take similar proceedings against him. It will, however, we may reasonably hope, render Mr. BARKER more cautious in his future proceedings; for it is not likely that, in any second trial of the same kind, he would be treated by the jury with equal leniency if again convicted of negligence.

INTERNATIONAL CONGRESS OF PATHOLOGY (TURIN).—The Congresso Internazionale dei Patologi in Torino will take place from Oct. 2nd to 5th, 1911, in the Institute of Pathological Anatomy of the University of Turin. The Congress will coincide with the jubilee festivities celebrating the Italian independence. An invitation, dated Feb. 10th, has been issued inviting pathologists to take part in the Congress, and is signed by Professor P. Foà and Professor B. Morpurgo. The offices of the Congress are at the Institute of General Pathology, Corso Raffaello, 30, Turin, Italy.

# Annotations.

"Ne quid nimis."

## NURSING IN THE FEVER HOSPITALS OF THE METROPOLITAN ASYLUMS BOARD.

ON Jan. 26th there came into force certain important changes affecting the nurses who staff the acute infectious hospitals of the Metropolitan Asylums Board. These alterations are the outcome of prolonged and careful deliberation by a special committee appointed for the purpose of reporting on the possibility of rendering the Board's fever service more attractive to the general body of women who take up nursing as a profession. In the course of its inquiries the committee was assisted by the opinions and advice of the matrons of the principal London general hospitals, and also by the matrons and medical superintendents of the Board's own hospitals. The three grades of nurses employed in the fever hospitals have hitherto been known as charge nurses, assistant nurses (Class I.), and assistant nurses (Class II.). In the acute hospitals they will henceforth be called sisters, staff nurses, and probationers. Sisters will receive a maximum salary of £44 a year as against a maximum of £40 for charge nurses, and will not be required to come on duty until 7.45 A.M. These alterations in the title and conditions of service, together with the prospect of obtaining a certificate of fever training at the end of 12 months' work, should prove an attraction to nurses who have just completed their training in the London general hospitals. Staff nurses will be paid a maximum salary of £30. Candidates who desire to join the Board's service as staff nurses must have had three years' training at a general hospital, Poor-law infirmary, or children's hospital containing at least 70 beds; or they must hold a certificate of fever training. It should be noted that when the new scheme came into operation on Jan. 26th charge nurses and first assistant nurses did not automatically become sisters and staff nurses, but only those who possessed the necessary qualifications and were recommended for promotion by the matrons and medical superintendents. Special consideration was given to the probationer section of the nursing staff, and some most important alterations have been made in the conditions of service in the hope of attracting to the Board's hospitals a larger number of women of good education. Hitherto assistant nurses (Class II.) have been liable to be transferred from one hospital to another, and to be given a month's notice when their services were no longer required, while they were unable to obtain a certificate of fever training. Such conditions were hardly likely to prove acceptable to women who desired to take up nursing as a profession. Under the new scheme a limited number of probationers will be appointed at each hospital who will not be liable to transfer, while if they are considered satisfactory at the end of three months' probation the Board will undertake to retain them in its service until they have completed two years' work. During this time they will be given systematic instruction, both in the lecture room and the wards; and if they pass the examination at the end of their two years' training they will obtain a certificate of proficiency in fever nursing and be eligible for promotion to the grade of staff nurse. These are not inconsiderable inducements to enter as a probationer at one of the Metropolitan Asylum Board's fever hospitals, but there is yet another, and that by no means the least. Certain of the general hospitals have agreed to accept each year from the Metropolitan Asylums Board a fixed number of probationers who have satisfactorily completed two years' fever training, provided they are considered suitable by the matrons of those hospitals. Further, those general hospitals where nurses are required to join for four years have undertaken to count the two years' work under the Board as equivalent to one year's work with them, so that the Board's probationers will join those general hospitals as second year's nurses and be paid accordingly. As they can enter the service of the Metropolitan Asylums Board at the age of 21 it will be possible for them at the age of 26, after five years' work, to hold a certificate of fever training in addition to one of full general training. This attempt to establish a system of coöperative training between fever hospitals and general hospitals will be watched with interest. For the sake of the fever hospitals it is to be hoped that it will prove a success, but in any case the Metropolitan Asylums Board is to be congratulated on its adoption of the scheme to which the special committee, under the guidance of its chairman, Mr. Jackson Hunt, has devoted so much time and consideration.

## WHOLESOME BREAD.

WE have received a number of requests to make an analysis of samples of "standard" bread which have been submitted to us by interested persons. It is quite impossible for us to deal with the multiplicity of applications which have reached us. We approve of standard bread when that expression means simply that the flour used in making the bread is unimpoverished by methods of manufacture—that is to say, when the entire nutritive portions of the wheat berry are retained. In our opinion the husk or the bran should be excluded. Apart altogether from the more appetising qualities of unseparated flours and the more generous proportion of valuable nutritive bodies which they contain, there are also principles in them which favour the assimilation of their constituents, which are absent in the separated flours. The best guides to truly wholesome bread are its peculiarly attractive flavour, which is somewhat sweet, and its colour, which is a dull light brown. Fraudulent imitations consisting merely of separated flour coloured with bran are practically flavourless. We hope that the question, now that it has attracted public attention, will be dealt with thoroughly, as it is obvious that more harm than good may be done by the movement in favour of "standard" bread, unless some security is afforded to the public in regard to procuring a genuine article. We are inclined to believe that the public can protect themselves in this matter, but a Government inquiry might have its uses.

## WHY SURGEONS BECOME SURGEONS.

IT must have occurred to many a medical man, especially when at medical gatherings, to wonder, perhaps half-unconsciously, what influence had determined this person or that into the pursuit of medicine. A little insight into this personal aspect has a genuine fascination. Dr. Francis Reder of St. Louis, with the true American instinct, has displayed the courage of his curiosity as to how it happened that surgeons became surgeons, and addressed letters of inquiry on the point to a number of surgeons—German, Italian, English, and American—who have accomplished things in surgery. He received very cordial and gratifying replies from 39 correspondents, which he appends to the Oration on Surgery delivered by him at the annual meeting of the Missouri State Medical Association in 1910, and published in the journal of that association for November. And very interesting reading the replies are. As will be readily understood, in most cases more than one factor was at work to determine the result. Fifteen (among whom may be named Dr. Roswell Park, Dr. W. W. Keen, Mr. John Chiene, and Mr. J. Bland-Sutton) possessed a natural inclination from childhood, and in six of these (including the Mayo brothers and Mr. Thomas Bryant)

parental example played a part. Admiration of a particular teacher—of Billroth (by Czerny and Hacker), of Langenbeck, Novaro, R. F. Weir, Durante, J. R. Wood, of Czerny (by Steinthal), and of Lister (by H. O. Marcy)—turned the student's bent toward the surgical side of the profession in ten cases, and in two cases admiration of the work done by the family medical attendant played a part. Personal experiences of surgical intervention *in propria persona* influenced three, while two received the impetus towards surgical work through experiences respectively in the Franco-German war and the United States war of the Rebellion. An American surgeon of note (Dr. J. A. Wyeth) confesses to having been prompted by "an ambition to do things that the vast majority of human beings could not do or did not like to undertake," and is of opinion that "surgery requires more courage than I felt it necessary to have to charge a battery or to do dangerous scout duty." We fear that will depend on whether the sense of responsibility to others is more highly developed than that of mere personal safety. Six surgeons own up to the fact that it was just the fortunate concurrence of a special opening in surgery that turned their thoughts in that direction; while six others, among whom are Sir Victor Horsley and Mr. F. F. Burghard, made surgery rather than medicine their choice from a consideration of the greater certainty of the benefits it was capable of conferring, in their opinion, upon humanity and of the more tangible evidence of its results than those of medicine. A natural taste for mechanics impelled two to the surgical side of the profession, while one was impelled to take up surgery through the exigencies of gynæcological work. In many cases it is noticeable that the first trend of the mind towards the medical profession was influenced by natural science studies. Among these is Dr. Howard Kelly, whose further specialisation was determined by the fact that in the "eighties" gynæcology offered a large field for original work and investigation.

## HARDWARE IN THE STOMACH.

FROM time to time there appear in the medical journals extraordinary catalogues of foreign bodies found, usually at necropsy and much less often at operation, within the stomach of an insane person. Our Vienna correspondent this week describes two such cases. That such aggregations should be tolerated by the stomach for long periods of time is surprising enough even when they consist of soft and yielding substances, such as the hair which becomes matted together to form a hair-ball; but when post-mortem examination of a person who has never shown the smallest sign of gastric discomfort discovers within the stomach a multitude of metallic objects, sharp, rigid, difficult to swallow and dangerous to retain, the only possible explanation of such an extraordinary insensitiveness must be found in the fact that the metal-swallower had been demented for years. A truly remarkable instance of this insane propensity is the case of a mulatto woman, aged 33 years, admitted in 1903 to one of the Missouri State hospitals with acute mania, ending in dementia and caused by excess in cocaine and morphia. From this time until September, 1910, when she died in the hospital, she never showed the least sign of disease of the digestive system. The attendants often saw her picking up nails and pins, but no one had seen her swallow any. Death was due to nephritis, and until a week before her death she never refused her food. Dr. A. H. Vandivert and Dr. H. P. Mills, who made the necropsy and reported the case in the *Journal of the American Medical Association* of Jan. 21st, were surprised to find the fundus of the stomach stretched down in a long pouch which reached into the left iliac fossa and adhered to the parietal peritoneum in that region. In this sac lay a hard mass which proved to consist of a large number of foreign bodies, leaving a narrow channel for the transmission of food along the lesser curvature. Adherent to the peritoneum of the stomach was the great omentum, remarkably thickened, and enclosing a number of small abscesses which represented the points at which the foreign bodies had made a way through the wall of the stomach, general peritoneal infection being averted only by the omental adhesion. The mucous membrane of the stomach was atrophic throughout and ulcerated in patches; the submucosa was infiltrated with round cells, and the subserous connective tissue exhibited a general dense fibrosis. Ulcers and widespread erosion were also seen in the mucous membrane of the œsophagus. In addition to the foreign bodies in the stomach there was a needle in the œsophagus and another at the base of the left lung. The foreign bodies in the stomach weighed 2268 grammes (5 pounds avoirdupois) in the aggregate, after thorough washing, and consisted of 453 nails, 42 screws, 136 ordinary pins, 115 hair-pins, 105 safety-pins, 52 carpet tacks, 63 buttons, and a miscellaneous collection of bolts, metal nuts, teaspoon handles, thimbles, needles, beads, coat-rack hooks, fruit seeds, stones and pieces of glass, and all sizes and shapes of similar objects, the total number being 1446. The writers have arranged this scrap-heap in rosette form for purposes of photography, and have thus achieved an extraordinarily vivid picture of the possibilities of the human stomach.

## THE CENTRAL ASSOCIATION FOR THE AID OF DISCHARGED CONVICTS.

Mr. Winston Churchill is to be congratulated upon the initiation of an agency which will have as its duties the direction and coördination of the existing agencies which have hitherto sought to assist and control convicted persons after their discharge from prison. These agencies have worked with good results in some instances, with unavoidable failure in many cases, and with lack of success in others, due to inadequate means at their disposal, to waste of energy and overlapping, and to other causes which the new Central Association is instituted to prevent. They have also endeavoured to carry out a difficult task, which, indeed, might often be described as a hopeless one, without any direct provision for their assistance from the State, for whose benefit their work is done no less than for that of the individuals immediately affected. Under the new scheme a general council is to be formed, composed of two representatives from each of the following bodies—the Royal Society for the Aid of Discharged Prisoners, the Church Army Discharged Prisoners' Aid Society, the Salvation Army Discharged Prisoners' Aid Society, the Catholic Discharged Prisoners' Aid Society, the United Synagogue Discharged Prisoners' Aid Society, and the Borstal Association, under the presidency of the Home Secretary, with Sir E. Ruggles Brise as chairman, Mr. Wemyss Grant Wilson as vice-chairman, and Mr. Basil Thomson as honorary treasurer and secretary. It will be observed that the associations representing various phases of religious thought which have hitherto been associated with this particular branch of charitable effort are rightly represented upon the council, but it may be suggested that the usefulness of the new body would be materially strengthened by the infusion into it of a medical element. In a large proportion of cases those who come under the cognisance of the central agency will owe their position and their need for assistance, control, and supervision as much to defective mentality as to the other causes which contribute to turn potentially good citizens into criminals. There will also be others whose physical condition will have to be closely considered and appreciated before suitable aid can be administered, and the observation of such temporary physical

conditions as may be due to recent experience of prison discipline will form a useful subject of study for which the Central Association will have considerable facilities. The opportunity to investigate the conditions, mental and physical, of convicted persons who have regained their liberty has been enjoyed by the existing agencies but without the additional power to bring them directly to the notice of the Home Office, a power which an association the president of which is the Home Secretary himself must enjoy to the fullest extent. Such investigation could have no useful result unless made officially and independently of prejudice of any kind by men qualified by training and experience to make it. Under the authority of the new association it should be possible to conduct it simultaneously with the exercise of the benevolent object for which that body has been primarily instituted, and with only a limited necessary outlay which would be likely to be recouped in due course to the State by the saving of a proportion of the expenditure caused by recidivism.

## THE CARE OF SICK SAILORS IN GERMANY.

A CONVALESCENT home for German seamen has been built at Zehlendorf in the Grünewald, near Berlin, by a philanthropic association constituted, under the inspiration of the Emperor and Empress, in 1908 with this particular object. Convalescent homes there were for the army and for other professions, but none for the sailors. That has now been changed, for this home will take seamen of the Imperial Navy or of the mercantile marine, as well as soldiers from the colonial or protectorate troops, to the number of 60, and also their officers to the number of 15. Retired and half-pay officers may be received if there is room. No serious cases requiring much attention can be received and no contagious diseases. The accommodation and recreation rooms for men and officers are quite separate; there are smoking and writing rooms for each with all the foreign military and naval papers, and a good library. For their treatment there are douche, steam, and electrical baths, and even a small swimming-bath. There is central heating and electric light throughout. The association has provided the site and the house; the medical treatment and maintenance are secured by a charge of 3*s*. 6*d*. daily for each man, 4*s*. 6*d*. daily for junior, 5*s*. 6*d*. for senior officers. The navy has taken ten beds, and it is hoped the large shipping firms will each similarly annex others. The estate is a forest, of which few trees have had to be sacrificed to the building, and it is hoped that this sanatorium may be of great benefit to those for whom it is planned.

## A HISTORY OF THE CAVENDISH LABORATORY.[1]

AFTER having successfully provided in the years 1864 and 1865 accommodation for the study of zoology, comparative anatomy, human anatomy, chemistry, mineralogy, and botany, the University of Cambridge turned its attention to the needs of the students who wanted instruction in heat, electricity, and magnetism. The prospect of expenses, however, very nearly defeated the good intentions of the syndicate which was formed to this end and which reported in favour of founding a special professorship and of supplying the professor with the means of making his teaching practical. It was not until October, 1870, that the opportunity came for making a real start with the Cavendish Laboratory. The Duke of Devonshire expressed a desire to carry out the recommendation of the syndicate, adding that he would be prepared to provide the funds required for the building and apparatus. Owing to a decision of the heads of the Colleges that the sums required under the Cambridge Improvement Acts should be levied by assessment instead of being charged on the University chest, the already heavy burden upon it was lightened, and amongst the new professorships founded was that of experimental physics, and the first professor of the Cavendish Laboratory, that distinguished physicist James Clerk-Maxwell, was elected on March 8th, 1871. The inaugural lecture was delivered on Oct. 25th in the same year. Clerk-Maxwell was succeeded on his death in 1879 by Lord Rayleigh, who in turn resigned in favour of the present professor, Sir J. J. Thomson, in 1884. In 1909 Sir J. J. Thomson completed the twenty-fifth year of his tenure of the Cavendish professorship, and it was this fact which gave rise to the suggestion by his immediate colleagues that the occasion should be celebrated in some way which would fitly commemorate a tenure so long and so full of achievement. A most interesting volume recording the history of the Cavendish Laboratory has since been issued, and it forms, we think, a very appropriate consummation of the foregoing suggestion. The University of Cambridge may well be proud of the valuable contributions which have been made to physical science as a result of the foundation of its Cavendish Laboratory, and it has been said with truth that perhaps there is no post in the world which has been held successively by three men of such great and such varied genius as Clerk-Maxwell, Rayleigh, and Thomson, who have made the Cavendish Laboratory known throughout the world. The transactions of the learned societies record what valuable work has been done, and it is now most interesting to discover in the book referred to how that work came to be done, in a series of monographs contributed by competent writers like T. C. Fitzpatrick, Arthur Schuster, R. T. Glazebrook, H. F. Newall, E. Rutherford, C. T. Wilson, N. R. Campbell, L. R. Wilberforce, and the present professor himself. The history is a splendid record of scientific work and education.

[1] A History of the Cavendish Laboratory, 1871–1910. With three portraits in collotype and eight other illustrations. London: Longmans, Green, and Co. 1910. Pp. 342. Price 7*s*. 6*d*. net.

## DIPHTHERIA OF THE VULVA IN A CHILD.

DIPHTHERIA of the vulva or vagina is very rare, and has been observed in two conditions—in the puerperium and in children. In 1898 Whitridge Williams recorded the case of a woman who on the twelfth day of a normal puerperium began to complain of pain and swelling in the vulva. The inner surface of the labia majora and minora was covered by a greyish-white membrane which extended a short distance up the vagina. The diphtheria bacillus was found, and recovery took place under antitoxin. The infant and an elder child were subsequently attacked with diphtheria and died. In necropsies in cases of puerperal septicæmia dirty-greyish or yellowish membrane is frequently found in the uterus and vagina, and has been described in the older works as diphtheria, but is generally due to necrosis produced by the streptococcus or other organism. Very few cases of diphtheria of the vulva in children have been recorded. It may be primary or secondary to diphtheria of the throat. In the *New York Medical Journal* of Jan. 7th Captain L. L. Smith, of the Medical Corps of the United States Army, has reported the following case. On March 15th, 1910, he was called to a girl, aged three years, who was suffering from slight cough with a little pyrexia. The throat and nose were examined with negative result, and in a day or two she seemed to have completely recovered. A few days later he was again called to see the child, as attempts to micturate were unsuccessful and caused her to cry with pain. The meatus urinarius and labia minora were slightly inflamed and swollen. There was some mucoid vaginal discharge, but no membrane was seen. As hot applications to the vulva and lower abdomen failed to produce micturition a catheter was passed. The urine was

normal. An alkaline diuretic was prescribed and micturition became possible but attended with great pain. The temperature was 100° F. On the next day there was slightly muco-purulent vaginal discharge, which was examined for the gonococcus by Gram's method with negative result. As there was no evidence of diphtheria of the throat or nose, this disease was not suspected and cultural methods were not employed. On the following day the discharge had increased slightly and there was some exudation on the labia minora, but no well-defined membrane. The inguinal glands were slightly enlarged and tender. A blood serum agar tube was inoculated and sent to the curator of the Army Medical Museum in order to determine the character of the infection. He reported that the specimen showed an almost pure culture of the diphtheria bacillus. Eight thousand units of antitoxin were administered and within 24 hours the urinary symptoms began to subside. Five thousand units were subsequently given and in a day or two the symptoms had disappeared. A slight greyish membrane separated from the labia minora and from part of the labia majora. Complete recovery without any complications followed. As soon as the infection was found to be diphtheria, and before antitoxin was administered, blood-serum tubes were inoculated from the secretions of the nose and throat with negative result. The only source of infection which could be suggested was a female guest from a locality where there had been cases of diphtheria. She visited the family two days before the child was taken ill and had a bad "cold," but was not ill enough to seek medical advice. She used the bathroom is which the child was bathed daily. Possibly a towel used by her was also used in drying the child, who was thus infected by a diphtheria carrier.

## "INFLUENZA" AMONG CATS.

As to whether the members of the feline tribe can rightly be set down as the subjects of "influenza," such as is understood by the term when applied to the human species, is a point upon which there has been considerable controversy. The differential diagnosis between "influenza" and "distemper" is often only a matter of opinion, and most veterinary surgeons would diagnose the ailment under the latter name. Distemper of the cat is a well-recognised complaint and very often occurs in such a virulent form as to clear out a whole cattery, causing a loss to the owner in some instances of many hundreds of pounds. In several parts of England at the present time epidemics of distemper are raging in a most fatal and virulent form, and veterinary experts have been called in wherever the value of the animal has permitted of the adoption of such a course. It is well recognised that the disease is spread very rapidly by the habits cats acquire of associating together, especially at night time, and that it is a disease which is very difficult to treat satisfactorily owing to the obstinacy and lack of vital resistance of the patient. A cat taken ill with this disease voluntarily refuses all nourishment and will die if not properly and artificially fed and kept thoroughly warm. In some instances the digestive system becomes affected, ulcers appear in the mouth, and there is a persistent diarrhœa and dysentery. In other cases the throat is violently inflamed, saliva streams from the mouth and lips, and the poor beast looks the picture of abject misery. Although it has never definitely been proved that this disease has actually been transmitted to man, it is certainly a wise precaution for the medical adviser of a household to insist upon the strict isolation, especially from children, of a cat suffering from any symptoms of this kind. In some instances death occurs within three days, but in most cases the cat will linger for a week or longer. Recovery is never certain, but when a cat has begun voluntarily to feed again the convalescence is tolerably rapid. Knowing from the daily press that the disease is prevalent just now among cats, we think that it would be an exceptionally good opportunity for practitioners, who may happen to be in infected district, to endeavour to trace up authentic instances of infection from cat to man.

## BILHARZIA IN EGYPT.

Dr. E. Zweifel, of the German Deaconesses' Hospital in Cairo, has very carefully examined the blood in 20 cases of the prevalent "Egyptian chlorosis," and has reported his results in the *Archiv für Schiffs- und Tropen-Hygiene* for February. In all of them bilharzia ova were found in either fæces or urine, but only five could be said to be infected with ankylostoma, which is usually declared to be the cause of the disease. He quotes with approval Kautsky's statement that the healthy lower classes in Egypt have a hæmoglobin content in their blood only 80 or 90 per cent. of that in Europeans, while in persons infected with bilharzia this is reduced to 70 per cent., and is not further lowered by an added infection with ankylostoma. The red corpuscles are reduced to 4,500,000 per cubic millimetre; the colour index is less than unity; the leucocyte count approximates 9750 in uncomplicated bilharziosis, but goes down to 8000 if ankylostoma is present as well; mononuclears are reduced, and eosinophiles are always increased. Full details are given and should be compared with the account of 50 cases in the paper by S. R. Douglas and F. W. Hardy that appeared in THE LANCET of Oct. 10th, 1903, p. 1009. The writer concludes that bilharzia is very prevalent in Egypt (he says that hæmaturia is almost universal and scarcely considered abnormal), and as it sets up a severe anæmia materially weakening the working power of the men, it is clear that it must materially diminish the work done in Egypt, the earnings of the people, and therewith, the revenue. So the Administration may find it well worth their while to spend money on investigation of the disease with a view to prevention and subsequent and consequent increase of the revenue hereafter.

## CONCERNING PRESCRIPTIONS.

A CORRESPONDENT under the pseudonym "Lex" recently informed us of a curious question which had come under his notice with regard to the prolonged and repeated use of prescriptions and to the rights with regard to them which may be claimed by patients. A druggist made up a prescription for a patient more than 12 years ago, kept a copy of it in his books, and from that copy dispensed the prescription on subsequent occasions for the benefit of the same customer. He has recently been asked by a solicitor, who is a relative of the patient, and presumably has the patient's authority for making the demand, to supply a copy of the prescription, and he has replied by declining to do so. "Legal proceedings" have since been threatened, presumably with a view to compelling the druggist to make from his books a copy of the copy contained in them, and to hand it to the patient who at one time obtained the original from a medical man and who possibly has lost it. We suggest another possibility with regard to the somewhat singular demand, as to the supposed motives of which we are not informed—namely, that the copy may be desired for comparison with the original in order to ascertain whether the medicine supplied is that ordered by the medical adviser of the patient so many years ago. Possibly it may not be found so efficacious now as when it was dispensed for the first time, but we are not concerned at the moment with the question whether a patient is wise to take during an indefinite period a medicine ordered on

some previous occasion by his medical attendant, but with the allegation of his right to a copy of a druggist's copy of the document ordering it. So far as the information before us enables us to do so we have considered the matter and on our side we ask this question: In the absence of any express contract to supply copies at any future date on demand, is there any contract to do so on the part of the druggist to be implied from what takes place when a patient brings him a medical man's prescription in order that it may be made up? In the ordinary circumstances of such a case we cannot conceive that there is any implied contract of this kind, and apart from a contract express or implied we do not see how any right enforceable by law to have a copy so made can arise. We are not aware of any custom requiring a druggist to furnish copies of prescriptions on demand, or of any case in which such a claim as that described has been carried into a court of law, and we hope we shall be informed if legal proceedings in fact follow upon the threat described by "Lex." Of course, legal proceedings are conceivable in which the court might order a dispenser to produce his books, but that is not the point we are considering. We have not considered closely what might arise in defence as to a time limitation for the enforcement of such a contract as we have suggested, for that would no doubt be gone into by the legal advisers of the threatened druggist after the first step in the proceedings had been taken by the other side.

## SLEEPING IN THE OPEN AIR.

IN the January number of the *British Journal of Tuberculosis* there is an interesting article by Dr. Thomas Spees Carrington, assistant secretary of the American National Association for the Study and Prevention of Tuberculosis. It is entitled "Directions for Living and Sleeping in the Open Air," and is written primarily for the instruction of patients in America desirous of carrying out the principles of the open-air treatment of tuberculosis at home, but English readers will profit from its lessons. The article is written simply and is admirably practical, full directions being given and the approximate cost of any apparatus or building recommended being stated. The best methods of constructing outdoor shelters, of building small shacks or cabins on the flat roofs of tenement houses, and of arranging for the patient to sleep and live in a porch or verandah under open-air conditions but sheltered from wind, rain, and snow, are clearly described and illustrated by photographs. When such constructions are not practicable, as, for example, in tenement houses in cities, the use of a bed tent is recommended, and full directions are given for its construction out of simple and inexpensive materials. The use of bed tents is more common in the United States than in this country, and is certainly worth a trial. The patient's bed is placed alongside an open window and a small canvas tent is erected over the patient's head and attached to the casing of the window and to the bed, so that the head and shoulders are practically in the open. Useful and ingenious contrivances are described composed of mosquito netting fixed over barrel hoops to cover the patient's bed completely, so as to act as a protection from mosquitoes and flies in tropical climates. Directions are given in regard to clothing, the making of the patient's bed, the arrangement of pillows, and protection from draughts. Among many useful hints in which the article abounds we may mention the suggestion that two pillows should be placed in the form of an inverted V, the apex being at the top of the bed, and the patient's head lying where the two pillows meet, so that his shoulders nestle between them and are protected. It is also advised that to prevent chilling the patient should get into bed indoors and then be wheeled into his outdoor shelter if this is practicable. Dr. Carrington's article is well worth perusal by any practitioner who has tuberculous patients under his care, and might be read also with advantage by the friends of those suffering from the disease.

## THE FUNDAMENTAL BASIS OF THE VOCATION OF MEDICINE.

THE persistent attempt to commercialise the profession of medicine that may be seen operating in varying degrees throughout the civilised world is defended by its supporters by the argument that this is essentially the commercial age. More and more are we urged to consider the fact that after all the practice of medicine is a business, in that it is a means of livelihood, and that consequently it ought to be conducted on business methods. This argument has cropped up in the recent perennial discussion on medical fees. "Senior," who started the correspondence in the *Times*, displayed all through his letter an underlying incapacity to understand that there need be any essential difference at all between the practice of medicine as a means of livelihood and any other business occupation. Yet it is undoubtedly the case that in all times the highest and worthiest thought in medicine has considered that there is a fundamental and unbridgeable chasm between the practice of the healing art and all commercial pursuits of whatever kind. The general principle on which this decision is based has been incisively and lucidly enunciated recently by Dr. Robert T. Morris in his report as trustee of Cornell University. In dealing with the subject of medical education Dr. Morris says: "The law of survival of the fittest does not work out in the professions as it does in the trades, because it is the public that has to bear the consequence of competition among physicians, and the fittest to survive is not always the one who represents the best interests of the public and of the profession." Method is, of course, as desirable for physicians as for anyone else, it is absolutely essential in science, and consequently in that aspect of medicine which depends on science. It should be cultivated in the extra-scientific aspects of the practice of medicine—the obligations between the medical man and the public—and in so far as the word method is synonymous with business the medical practitioner should surely be business-like. But his methods must be the special methods that accord with the spirit of the above-mentioned general principle—not the "customs of the commercial world." These, worthy of respect though they may be at the hands of the commercial man, are based upon first principles essentially different from those upon which the practice of the healing art has been from time immemorial established.

THE Local Government Board has issued an Order enabling the Metropolitan Asylums Board to utilise spare accommodation in the hospitals of the Asylums Board for the reception and treatment of additional classes of poor persons. Under the authority thus conferred upon it the Asylums Board will be enabled to receive from any of the Poor-law authorities of the metropolis children suffering from measles or whooping-cough into any of its hospitals or parts of its hospitals where there is vacant accommodation. It is understood that some 1000 beds will be available for these cases.

ON the retirement of Dr. Franklin Parsons, assistant medical officer of the Local Government Board, and Dr. Bruce Low, second assistant medical officer of that service, Dr. Theodore Thomson and Dr. G. S. Buchanan have been appointed respectively to these posts. Dr. Buchanan, for the last five or six years, has acted as chief inspector in the new division of the medical department which has been set up

to deal with questions of the purity of food and the prevention of adulteration.

THE number of small-pox cases in the epidemic in the East-End of London had reached over 40 by the middle of the week. Close supervision of suspects is being practised.

Professor W. E. Dixon, Professor W. H. Lang, Professor R. Muir, and Professor J. B. Leathes are among the candidates recommended by the Council of that body for election to the Royal Society.

## BONE-SETTING AND ITS GENERAL PRINCIPLES.

BY FRANK ROMER, M.R.C.S. ENG., L.R.C.P. LOND.

SINCE Dr. Wharton Hood in 1871 described from personal observation the methods employed by Hutton, a leading bone-setter of the day, many surgeons have adopted, with satisfactory results, similar or modified principles. This article is submitted with the object of dispelling the popular notion that the medical profession know nothing of bone-setting, while at the same time drawing attention to the general principles which should be observed in dealing with joints whose utility has been impaired by adhesions. No useful object will be served by describing the pathology of the various ankyloses, and for the purposes of this article it may be assumed that reference is made to fibrous adhesions caused mainly by trauma. Again, though treatment by bone-setting is usually rapid and effective, it must be remembered that a cure could in many cases be achieved by electricity, prolonged massage, or other means.

Adhesions may appear within three weeks of the injury, but their capability of interfering with the action of a joint depends to a large extent on their situation. They may exist within the joint itself, binding together the articular surfaces and folds of synovial membrane, or be entirely periarticular when the surrounding tendons have become adherent to their sheaths through tenosynovitis. The resulting disability may vary from complete ankylosis of the joint to a condition where pain is only elicited by some particular movement. An important point to bear in mind is that a joint need not be entirely incapacitated by adhesions to require manipulation. Indeed, in these days of early massage and movement complete ankylosis is rare compared to what it was in the time when absolute rest was considered essential for the treatment of bone and joint injuries. Hence it frequently happens that the possibility of some small adventitious band is not suspected, provided the joint moves with comparative freedom, and it is especially in these cases that the modern bone-setter proves so successful. Careful examination in such cases will reveal a painful though comparatively slight interference with the normal range of movement, to cure which forcible manipulation will be just as necessary as in joints whose action is entirely crippled by adhesions. Some authorities state that previous to attempting these operations on ankylosed joints careful preparation for a week beforehand by hot fomentations and massage is essential. These preliminaries are not needful, though perhaps in certain cases of long standing, where the whole limb is stiff from disuse, a few radiant heat baths combined with massage might prove useful by rendering the muscles more supple. Again, it has been suggested that in such circumstances tenotomy should be previously performed, but proper attention to the after-treatment makes this a quite unnecessary procedure.

Unless contra-indicated, when adhesions are to be broken down an anæsthetic must always be given, not so much for the avoidance of pain as to ensure complete relaxation of the muscles. By dispensing with an anæsthetic the difficulties of the operation are increased, as it will be necessary to overcome muscles which the patient will involuntarily put into action for the protection of the joint, before the adhesions can be satisfactorily ruptured; at the same time, a risk is run of severely spraining or rupturing the contracted muscles. It is for the same reason that nitrous-oxide should not be selected as the anæsthetic, and it is possible that where severe inflammation has followed forcible movements these points have not been observed. Where manipulation has been properly performed no untoward result need be feared, as there is nothing in the rupture of fibrous bands to cause inflammatory action provided the case is otherwise suitable.

Generally speaking the movements should be performed in a swift, even, and firm manner, so that a joint undergoes the motions of its normal action, though not necessarily to the full extent of its range. The reason of this is that the muscles will have contracted in proportion to the limitation of movement permitted by the adhesions, and once that limit has been overcome the contraction of the muscles will be the only impediment to the normal range. The adhesions once ruptured after-treatment will speedily restore the elasticity of the muscles, which might well be strained should the full extent of movement be at once sought. In cases of long standing the adhesions yield with a distinct audible snap or crackle, others of less duration with the noise of tearing wet parchment, whilst those of still more recent date, though giving no audible sound, can generally be felt by the fingers of the operator. Experience shows that rapidity in the execution of the movements gives rise to far less after-pain than if the adhesions are broken down by slow and deliberate stretching, but care must be exercised against jerks or undue violence. When taking hold of a limb the grasp should be just above and just below the affected joint, for though a more powerful leverage can be obtained by more distant grips, yet it is as well to bear in mind that other structures may be broken besides adhesions, whilst in the young there is danger of separating the epiphyses.

After-pain is certain to be present in varying degrees, but will pass off in the course of an hour or so, and provided sufficient care has been taken in the operation no apprehension need be felt on this point. Within a few hours the joint should be gently massaged and movements aided. The mere allowing a joint to remain quiescent for 48 hours, as is sometimes recommended, is not safe; sufficient time may thus be given to allow the freshly ruptured adhesions to reunite. Notwithstanding the pain, every effort should be made to keep the joint free, and on no account should any bandage or splint be applied. It will be found that the rubbing, if skilfully performed, gives great relief from the pain, and any local application is scarcely ever requisite.

Occasionally full movement and freedom from pain follow the manipulations, but this ideal result is rare. More often a patient is quite unable to move the joint beyond the extent obtained under the anæsthetic, the explanation being that though there is no longer mechanical obstruction in the joint, the muscles from disuse are so wasted and contracted that they are physically incapable of normal work. To dismiss a patient without correcting this condition is to court almost certain failure. Merely ordering the joint to be used is for the most part useless, as few people have the strength of will necessary to make muscles perform their proper functions at the expense of pain. It is the custom of a large number of bone-setters to administer an anæsthetic on two or three subsequent occasions for the purpose of overcoming the muscular resistance. This should never really be necessary if the adhesions have been properly dealt with at the time of the operation, and the most satisfactory treatment after the first two days consists in substituting for the rubbing graduated exercises by means of weights and pulleys. These exercises, though possibly painful, must be performed daily, when it will be found that increase of strength and mobility bring decrease of pain. Exercises should be diligently persevered in till the muscles have regained their former bulk and the joint its full power of movement.

Such are the broad principles upon which bone-setting is based, and, though in certain particulars the procedure I have set out differs from that advised by some surgeons, it embodies the experience gained in a large number of cases, in which success has followed its adoption. Doubtless many joints affected by small adhesions might eventually recover by other means, but the facilities of radiant heat and massage are not easily come by in country places, and are moreover expensive. Where perfect recovery from effects of trauma is unduly delayed time is too often considered as the only solution of the difficulty, and when the patient, tired of his disability, seeks unqualified advice, his cure by the aid of "bone-setting"

must not be regarded as one of "suggestion." Contrary to the popular belief that some mysterious gift is essential for the successful performance of these manipulations, there is nothing to prevent any practitioner doing them with success, provided that care is taken to ascertain the particular lesion that exists. A certain delicacy of touch is doubtlessly requisite to properly appreciate that lesion, whilst the correction of it largely depends on knack, but both can easily be acquired by experience and practice.

## THOMAS v. BARKER.

### MR. JUSTICE DARLING'S SUMMING-UP.

**IN the High Court of Justice, King's Bench Division, on Tuesday and Wednesday of last week, before Mr. Justice Darling, this important case was tried.**

**The following is a transcript from the shorthand notes of Messrs. Marten, Meredith, and Co., 8, New-court, Carey-street, London, W.C., of the summing-up of the learned judge, in the course of whose remarks the gist of the medical evidence becomes apparent as it struck an acute and impartial lay critic. The reasons both for the verdict in favour of the plaintiff and for the modest amount of the damages will be obvious.**

*Summing-up.*

MR. JUSTICE DARLING: Gentlemen, you are aware that this is a case in which the plaintiff seeks damages from the defendant, Mr. Barker, because he says he has established before you, and it is for him to establish it, that Mr. Barker, undertaking to treat him for some affection of the knee, treated him without the amount of skill which he was entitled to expect from Mr. Barker, and that thereby the plaintiff suffered damage in money to the extent of £400, and damage in this, that he had to have the leg amputated, which he would not, he says, otherwise have lost. Now, gentlemen, I tell you that it is for the plaintiff to satisfy you, or else your verdict must be given for the defendant, that the negligence alleged against the defendant is made out. As to what that negligence should be, it is conceded that the defendant is a very skilful manipulator of bones; he is not a man who has passed examinations and got degrees, but has been a long time at this business, and everyone admits and it cannot be too well remembered that he has a great amount of skill and practice in dealing with affections of joints, dislocations of joints, as well as other injuries, which people may suffer from in their joints and limbs. That being so, he is bound to use the best of his skill and knowledge, and it will not do for him to say, and he does not say: "I am only a poor ignorant man, and I did my best." What he says is this: "I am a skilful man, I am a man who has performed thousands of remarkable operations resulting in cure where ordinary doctors have been less successful," and it is because of that reputation that the plaintiff went to him, and therefore the plaintiff is entitled to expect a reasonable amount, a fair and proper amount, of the skill and knowledge of the defendant to be placed at his disposal.

Now, gentlemen, there are some things in this case which we may take absolutely for granted. If I state anything that is not to be taken absolutely for granted I hope the learned counsel against whom I state it will interrupt me at once. The plaintiff had long been suffering from a state of knee which it is now admitted had resulted in a tubercle affection of the knee of some long standing. He hurt his knee in 1901; it had been bad off and on in 1905 and 1906 and 1908; he had been at the Charing Cross Hospital, where the surgeons had suspected tuberculosis; what is called a radiograph had been made of his leg, of the joint, by the skilful photographer and doctor there, and he had come to the conclusion that then in 1908 at the Charing Cross Hospital the plaintiff was suffering from a tuberculous affection of the knee-joint. Now we start with that, and that is before he sees the defendant at all. It may be also taken for granted that nothing that the defendant did, whatever it was, did produce or could have produced the tuberculous affection of the knee-joint; it is admitted that the tuberculous affection was present before. Now we know what has only lately been known, for a very few years even to doctors, but it is now common knowledge that tuberculosis is the work of a little microbe; it is called a little bacillus, a thing that can be identified under the microscope, a thing that can be differentiated from other bacilli, so that a doctor will say, "That is a bacillus which produces tuberculosis; that is a bacillus which produces cholera; that is the bacillus which produces some other definite disease." These things are known. People knew long ago that there was such a thing as tuberculosis, and they called it tuberculosis, and they knew long ago that if you got a tuberculous joint you should keep it quiet, but they did not know why. But now the doctors know why, and the reason is that the bacilli are warring against the tissues in the human body, but among what the doctors call the forces of nature—the bacilli also ought to be recognised as the forces of nature, it seems to me—among the other forces of nature there is something at work, what it is we have not been told, but it is something at work which fights the bacillus, and what it does to him is to cover him over with an envelope. If you keep the place quiet where he is at work and cover him over with an envelope and imprison him, as long as he is there he is like the genius which the Eastern emperor put into the bottle and which the fisherman released unskilfully, not knowing he was there. While there imprisoned he is like the genius, he can do no harm, but take him out, release him, and he becomes active at once. He finds his way to the most vital parts of the body and he will kill the patient in whom he is operating, unless he is removed by some such process as the amputation of the affected limb. Now that happened here. Somehow the bacillus was at work in Mr. Thomas, and had been for a long time. Some of the doctors, the doctors on the one side, said, "We believe he was quiescent; we believe he had become quiescent; we believe he was imprisoned, encapsulated, use whatever term you like, and it would not have done him harm if it had not been interfered with." The doctors on behalf of the defendant said this afternoon, "We do not agree at all." They said, "We had not the same advantage; we had not the same opportunity as the plaintiff's doctors, because they saw the plaintiff while he had his leg upon him, they saw the sinus, they saw the abscess, they took off the leg, they examined while it was fresh, bone, cartilage, tissues, and everything," and they were called yesterday and gave their evidence. The doctors called by the defendant to-day say, "We have not had that advantage, we have examined the thing since it has been preserved in formalin, and we come to the conclusion that the microbes had not been encapsulated; that this was a thing of long standing; that it was a progressive thing; it did become more active than it had been; it did result in such a thing that by the 15th April it was necessary to amputate the leg or the man would have died." They all agree to that, but the defendant's doctors say that was in no way due to anything the defendant did, it would have happened anyhow. Then it becomes necessary to inquire what did the defendant do? Here, again, it is conceded on all hands, unless I am much mistaken, that it would have been grossly improper, with a leg being in the state in which it was in November, 1909, and December, 1909, to do any such thing to it as the plaintiff suggests was done. It would have been grossly improper, the defendant himself says, to have used any violence to it, to have attempted to break down adhesions by giving it a violent wrench.

Now, gentlemen, it is also admitted that in certain circumstances it is a perfectly proper thing to take hold of a joint and to use violence to it to break down adhesions. It is stiff because something has grown on to it and holds it tight, and it is admitted that there is a legitimate operation of breaking down adhesions, and then the joint will work. But it is admitted that must not be done if the joint is a joint affected by tuberculosis, and it must not be done for the reason that if you do that kind of operation upon a joint affected by tuberculosis you set free the bacilli and they do the work which I have just described to you. Now the contest comes between the plaintiff and the defendant. The plaintiff says the defendant did undertake to perform an operation upon him, the operation of breaking down the adhesions; he told me that he would have me dance, which he could not do while these adhesions were there. The defendant says, "I never undertook to do anything of the kind; I told you you had tuberculous disease of the joint." The plaintiff says "You did say something about tubercle, we talked about it, because I said the doctors at the Charing Cross Hospital suspected something of the kind." The defendant says, "I told him that I must examine him, and I should recommend radiant-heat baths, and I should want to examine the knee." The plaintiff said, "You told me you must give me an anæsthetic because the operation you were going to perform would cause me great pain." The defendant says, "I never said anything of the sort. I wanted to perform no operation. I wanted to make an examination," and therefore the defendant says—I will read it if you wish, but I think I can summarise it—"I recognised from the first this was a very bad knee. I suspected there might be cancer it was so bad, sarcoma it is called. I never expected even to be able to give relief, but I said I will try these radiant-heat baths and make the examination, and I shall want, for the examination, to give you an anæsthetic." Gentlemen, he did prescribe the heat baths, and the plaintiff took them, and he went back, and on two occasions, the 27th November and the 16th December, the defendant got Dr. Axham, his anæsthetist, to give gas to the plaintiff. While under gas he did something to the plaintiff, and he did it with his hands. The defendant says, "What I did was I handled him very gently, I simply moved my hands during a few seconds to make an examination." Why did he do it? He said, "I did it to confirm myself in my opinion. I had made a hurried examination before, and this was to satisfy myself whether my first opinion about it was right." If the very first examination, the one on the 27th November, did satisfy him be was quite right that it was tuberculosis, that there was nothing to be done, the case was hopeless—he said himself there was nothing for it but amputation, and that he told the plaintiff so, and that he must see a surgeon—If that is so, how is the second examination explained? What is said is, if you are going to treat a leg in the way of breaking down adhesions, if you do not break them all down the first time you will have to perform a subsequent operation. That is common enough, but it is asked, If he had made an examination under gas and satisfied himself by that examination of the 27th November that he was right in his diagnosis, why put the plaintiff to 5 guineas more expense to make another examination? The answer to that is that it was done to see what effect the radiant-heat baths had produced. Now are you satisfied of that? Dr. Axham has been called, you have heard his evidence. I will not attempt in any way—it is so lately given and it would be impossible to summarise it in a few words—to convey any idea of it. You have heard it. Does it satisfy you no operation was performed on that day? Does it satisfy you there was nothing else? You heard his examination and his cross-examination. There is the fact of what is put down in the books. You see "Op. gas" and those two letters and you have heard the defendant's explanation of what that means. They are the very words he puts down when he does do an operation, when he does operate by breaking down adhesions. There is nothing to distinguish them, but he says: "It merely means I wanted the anæsthetist; it does not mean there was an operation, it merely means gas." Gentlemen, I suppose you will ask yourselves: If it only means gas, why not put down only "Gas": why put "Op. gas," which is put when there is an operation under gas, if you do not mean any operation but only mean gas? But there is his explanation. It seems certain that gas is quite sufficient if you are only going to do such an operation as can be done by a very skilful man, a very quick man. Gas is quite sufficient if a skilful practised man is going to break down adhesions, to take hold of a limb, twist it, and break down the adhesions. It might take you or me half a day, but a man who knows exactly what to do can do it; and the defendant habitually does do it with gas. When he wants to perform an operation he puts "Op. gas," and then he performs an operation not with chloroform or ether necessarily, but with nitrous oxide gas. If that is so, you must ask yourselves are you satisfied what was done on these days was nothing but examination. If it was nothing but examination the plaintiff's case is gone, because nobody pretends that merely to examine that knee without using the sort of violence that would be used to break down

adhesions would have produced the kind of thing the plaintiff said was produced by what was done on those two days. Here, again, mind, it is for the plaintiff to satisfy you that what was done was violent twisting or breaking down of those adhesions. He must satisfy you. If you cannot make up your mind about it you must not find for the plaintiff upon that, but you must take this evidence into your consideration and say what are you satisfied was done. The defendant's case is this, and he and Dr. Axham are the only two people who were awake in the room at the time what he did was done; the plaintiff, of course, was asleep owing to the gas. The defendant undoubtedly knows what was done, the plaintiff does not accurately; I mean he cannot tell you, he was asleep; the defendant does know what was done. Dr. Axham may or may not know what was done, according as you think you can trust his evidence as being genuine or with insufficient knowledge. But there are three witnesses whose evidence you must bear in mind in considering really what was done on the 27th November and the 16th December. It is admitted that the plaintiff took with him on the first visit his sister Alice, and she said she saw the defendant in a waiting-room. "I asked him if he thought he could do my brother any good; he said Yes. Defendant said my brother did not want to take an anæsthetic, but what he was going to do could not be done without one as it would cause intense pain." Gentlemen, if you believe that, that does not refer to an examination to satisfy himself as to whether his first diagnosis was right, because it is not pretended that an examination would cause any pain at all. Examination would be the gentle touching alluded to in the letter as a "gentle movement of the joint," to see if it was free or tuberculous. Do you believe that young woman when she says that was said to her? "The defendant said he was quite sure he could do my brother a lot of good, if he did not quite cure the limb that he could walk without a stick or anything." Now the defendant's evidence is totally different, because he says, "I recognised from the first I could not do him any good. I never pretended I could do him any good; it was a shocking case, a very bad case of tuberculous joint, as I could see the very first time when I made my first examination on the 27th November. I was absolutely confirmed by that, although he had those radiant heat baths meantime." That was said on the 2nd November, not at the time when any operation took place. But on the 27th November, when the first operation or examination was performed, the plaintiff undoubtedly took with him Mr. Joy, his cousin. We know he undoubtedly did, because the defendant himself says, "I saw Mr. Joy; I saw him in the waiting-room. I saw him as I came out," and Mr. Joy says this: "After the operation I saw the plaintiff; he was dazed and exhausted; they had all come into the ante-room; the defendant looked very heated, that is Barker; drops of perspiration were on his brow. I said, 'You seem very warm, Mr. Barker.' The defendant said, 'He has given me a hard job,' or a 'tough job.' I asked if the plaintiff was all right. Defendant said, 'Oh yes, we will soon see him all right.'" He says, "the plaintiff was in the defendant's room, where I was not, for 20 minutes or half an hour." Now, gentlemen, you must ask yourselves is that evidence true? If it is true it points to something being done very different from a little examination, and no one disputes that if a man is going, within a short space of time, something under a minute, to take a joint forcibly and break down adhesions, that is very hard work, and the defendant himself told us yesterday he worked very hard, that the work was hard and exhausting, and you could see for yourselves if you are applying your force with knowledge upon a very small space and within a very short time, it is bound to fatigue and to fatigue you suddenly and greatly. You must ask yourselves is that evidence true? If it is not true, Sir Edward Clarke said, and I see no alternative to it, Mr. Joy has simply invented it, and Sir Edward Clarke said it was perjury and very deliberate perjury. There he will have invented the fact of the appearance of the defendant, and invented a conversation with the defendant, and I do not see how you can help applying the same observations to the evidence I have just read of Miss Alice Thomas. Mind, you must not be afraid; juries must do their duty and must face most difficult circumstances bravely. It may be that is perjury, it is for you to judge: you saw the young woman; you saw Mr. Joy; you heard him give his evidence and you heard what cross-examination there was. Do you or do you not believe him?

Now Miss Elizabeth Thomas went with her brother on the 16th December, and she says, "I went with my brother; I saw the defendant before the anæsthetic was given, and again afterwards. The defendant came downstairs"—it was suggested at one time that could not be, that the consulting room was on the ground floor, but he has two, and sometimes uses one and sometimes the other—"and took me up to where the plaintiff was; the defendant looked very hot; the defendant left me alone with my brother and then came in again. I asked the defendant what he thought of my brother's leg; he said he thought it might be sarcoma, and said: 'It is a very bad leg.' I asked if he thought he could do my brother any good, and he said, yes, he thought he could. He said he felt quite sure we should have him walking about again." Then she was cross-examined and said, "I know now what sarcoma is"—the defendant says he believed he explained it to her and told her it meant cancer—"I inquired a few days later of one of our own doctors, it may have been Dr. Bunn or Dr. Carruthers, and I think he said it was something like cancer of the bone; this was in December, and I told him that is what the defendant had said the plaintiff was suffering from. I do not know that the defendant led me to believe that he had used great force; he looked very hot." There is her account.

Now, gentlemen, really it seems to me the crux of this case is what was done on those two days. Do you feel sure of what was done? Can you make up your minds upon the evidence of the plaintiff and of the defendant, and of Dr. Axham and of those three witnesses, what was done? Some of them are not telling you the truth, that is certain. If the defendant is telling you the truth the plaintiff is not, and I should say if he is telling the truth it is almost impossible to suppose that Mr. Joy is telling the truth, and very difficult to suppose these two young women are. What he says is absolutely irreconcileable with what Mr. Joy says. Now, gentlemen, you must make up your minds, I think, whether on those two days, the 27th November and the 16th December, an operation was performed or whether only an examination took place. As to these the defendant says it was only an examination; it was an examination, if an examination, under gas. He does use gas when he is going to perform an operation. Does anyone use gas except for operations? Does anyone use it for making an examination alone? The doctors for the plaintiff say no, but now here is a doctor called for the defendant, Dr. Garrard; he is a very eminent doctor, as Sir Edward Carson has pointed out. Listen to what he says about this: "I never have examined a knee of this kind with an anæsthetic; it is sometimes required to overcome reflex contraction; gas could not do the patient any harm; I should not have given it myself; I should not want to examine the joint; if so, I should prefer chloroform; gas is the least dangerous." That he said in examination-in-chief, but if he wanted to examine a joint he would not give an anæsthetic; he would not need to; he could examine the joint without. What bearing has that on this case? What was there here which made it necessary to examine that joint with an anæsthetic? What was there that the defendant had not found out about the joint in the interviews which preceded the 27th November and in what he knew had happened from the treatment of the radiant heat baths? Dr. Garrard was then cross-examined by Sir Edward Clarke and said this: "I have much experience of tuberculous joints. I have had to examine many tuberculous joints. A careful examination would take some considerable time." The reason for that is this: what was done by the defendant only took a few seconds, something inside a minute. It is conceivable an operation may be performed within that time, a sudden violent twist, but if you are going to examine in order to confirm earlier examinations is it enough time? Listen to what Dr. Garrard says: "A careful examination would take some considerable time. I have never used an anæsthetic for it, and have always made a satisfactory examination. I should prefer chloroform if I had to give an anæsthetic to examine a joint, because it gives a longer time and relaxation of the joint. Gas gives a very short relaxation; then the muscles become rigid, and so the purpose of the examination would be defeated." That is Dr. Garrard's evidence. Now ask yourselves, in the light of the scientific knowledge which these people place at your disposal——

A JUROR: May I make a remark, my lord?

Mr. Justice DARLING: Certainly.

The JUROR: The evidence seems so conflicting on the part of the doctors as to the immediate result of the breaking down of the adhesions. Some doctors say he could not walk away at all.

Mr. Justice DARLING: I was coming to that.

The JUROR: Others say it would not show for some weeks.

Mr. Justice DARLING: I know, and I will come to that. There you have the medical knowledge which is put at your disposal as to the object and as to the utility of giving gas to a person for an examination. That it may be given for an operation is not disputed, because it has been done. As you yourself have said, it has been said by the doctors, some on one side and some on the other, that the plaintiff would have been in such pain that he could not have walked away. He says himself, I will read it to you if you like, that directly this was done he did feel easier. If nothing was done but examine it was difficult to imagine that could have made him feel easier, but he says he did feel easier at the time; that he walked away with a stick, he came with a stick; that after a time the knee-joint got stiff and swelled. He went and had more of the baths; then the last operation was performed, after a time the knee-joint got stiffer, more swollen. Before he gave up attending the defendant at all there had appeared the inflammation on the outside, there had appeared the sore, and then he put himself in the hands of these other doctors. Now, gentlemen, what do the doctors say? On the one side they said if anything beyond an examination had been made, anything in the way of breaking down adhesions, he could not have walked away. Other doctors, Mr. Waterhouse and others, say he could. At the time there is nothing inconsistent. They heard all the evidence he gave, and they said there was nothing inconsistent in his having walked away from the place directly the operation had been performed. I cannot tell you how to reconcile this. You must try to find out some means for yourselves. It would be improper for me to say you should rely on this doctor more than on that. You have seen them in the box, you have heard them give their evidence, you have heard them cross-examined. You find that the doctors on the part of the plaintiff, Mr. Waterhouse, and the rest, see nothing inconsistent with an operation being performed on those two days and the plaintiff walking away and walking about some time afterwards, and finding the damage becoming noticeable some time after whatever was done was done. You have heard the cross-examination, a long cross-examination, as to whether it would not necessarily have brought about great pain and suppuration even within a very short time; whether the microbes would not have got to work at once and practically destroyed his life within a few days. The doctors on the other side, the same doctors who have given this theory you have lately listened to from the observing of that joint in the bottle, have given their opinion, and said he could not have walked away after an operation had been performed.

A JUROR: My lord, could we not know how many said he could and how many said he could not, because it seems to me to hang on that?

Mr. Justice DARLING: Dr. Bunn thinks he could, Dr. Carruthers thinks he could, Mr. Waterhouse thinks he could, Mr. Ballance thinks he could. There was one other doctor.

Sir EDWARD CLARKE: Dr. Ironside Bruce.

Mr. Justice DARLING: Not one of them saw anything inconsistent in his walking away as he said he did, with a stick and feeling stiffness and swelling after a time, after a day or two. Not one of them saw any inconsistency in his doing that, anything inconsistent with the fact that an operation—a wrenching—had been performed on him that day. He walked with a limp when he came—he came because he always walked with a limp, and he went away with a limp. The doctors you have heard this morning—Mr. Barker you are entitled to take because, although not a qualified doctor, he knows a good deal about this kind of thing—Mr. Barker, Mr. Garrard, Mr. Phillips——

Mr. HOLMAN GREGORY: Dr. Axham.

Mr. Justice DARLING: Yes, Dr. Axham.

Sir EDWARD CARSON: And Dr. Whitehead.

Sir EDWARD CLARKE: He did not say anything about it.

Mr. Justice DARLING: Dr. Whitehead did not say very much about it.

Sir EDWARD CARSON: He said that he agreed with the other doctors.

Mr. Justice DARLING: Yes, he did, he agrees with Dr. Garrard and Mr. Phillips. He also said to Sir Edward Clarke that he agreed with Dr. Garrard's evidence, and you have heard the points in that evidence; Sir Edward Clarke called Dr. Whitehead to his aid, the points in which he relied himself upon his evidence.

Gentlemen, that is the case, but beyond I ought to tell you it is never a good way in estimating the value of evidence to say there are so many

on one side and so many on the other, because if time enough is given to it you could in most cases find always enough witnesses to overbalance in mere numbers the witnesses on the other side. Gentlemen, you must apply your own common-sense to the evidence, apply your own knowledge of what would be likely to happen, and weigh the evidence given by the doctors and by every other witness with that knowledge in your minds; but also do this: when you have theory on one side and theory on the other, and you want to find out whether a particular thing did happen or did not happen, you must have something to go by beyond those who say if it did happen the consequences would be so-and-so, and those who say if it did happen the consequences would be the reverse. If you feel you have direct evidence upon which you can rely as to what was done at the time and said at the time, and you are entitled to satisfy yourselves by that, you are not bound to attempt to reconcile one theory with the other. If the evidence satisfies you a thing was done or was not done, you should say it was done or it was not done, notwithstanding that so-and-so says the consequences if it was done would be this, and somebody else says the consequences if it was done would be that. If you are satisfied by evidence a thing was done, what can it matter that people say if it had been done the consequences would have been so-and-so? Let me put a simple case. Suppose you go away from this building and see a man knocked down by a taxicab, as you very likely will, and you see him get up and run away, and suppose when you come back here a year or so hence the case is being tried and people were to come before you and say if a man had been knocked over by a taxicab he could not have got up and run away; he might have gone a yard, and another said he could not have moved at all, he would be lying there still; and suppose you find another witness saying if a man were knocked down by a taxicab not only could he get up and run away but he would run all the better, all the faster, because he was so frightened, you would say to yourselves, "I cannot reconcile these theories; these are theories, I cannot reconcile them." I would say to you, if you were trying that case, "For goodness sake, there is one thing do not do: do not count how many witnesses have been called for the plaintiff and how many for the defendant; satisfy yourselves whether the thing did happen or not." If you saw it happen you would have a simple way of saying, "I know it happened because I saw it," but you might have a way not quite as simple but yet sufficient; you might have this: a man might come and say, "I care nothing for theories, I saw that happen; I do not want to go into what the man could do; I saw it happen," and if that was a man whose evidence you felt you could trust you would say that did happen, or, if a man said, "I was there and it did not happen," you would say "I am satisfied it did not happen," and you would not want to ask yourselves what would be the consequences if this man is right, or the other. I am not telling you that this scientific evidence should not be taken into consideration; it should. It should be taken into consideration, and due and proper weight given to it, but the number of witnesses should not be counted as a means of finding out a preponderance of opinion. The weight of evidence should be watched and carefully considered, and to arrive at whether it is satisfactory evidence or not it should be compared with what you can satisfy yourselves to be the indisputable facts of the case, and some facts there may be you are satisfied are indisputable. I do not think there is anything more I need say to you. If there is any point learned counsel desire me to call attention to I will call attention to it, but I do not think there is. Gentlemen, you will find for the plaintiff, therefore, if he has satisfied you that the defendant treated him negligently and that damage was thereby occasioned. If he did treat him negligently some damage was certainly occasioned, because he paid the defendant, I forget how much.

Sir EDWARD CLARKE: 17 guineas, my lord.

Mr. Justice DARLING: And if he paid 17 guineas for doing that which was worthless some damage was occasioned. Of course, if you find for the plaintiff it does not follow all the damage which the plaintiff says occurred to him occurred to him because of what the defendant did, even if what the defendant did was negligent, because there still remains, as Sir Edward Carson put, this possibility, that even if the defendant was negligent what he did may have had the smallest possible effect upon the sufferings or the losses of the plaintiff outside the loss of the 17 guineas. It may be that those microbes would have become active if the plaintiff had never seen the defendant. You may say to yourselves you are satisfied they would, or you are satisfied that they would not. You may say to yourselves you are satisfied if you find the defendant did do that which is negligent to the plaintiff, that but for that the plaintiff would not have had to pay this £400 and lost his leg, but it is only if you are satisfied of the negligence and of the resulting damage from it that you may give a verdict for the plaintiff with a sum commensurate with what you find to be the result of the damage. Gentlemen, you will take the case into your consideration and say whether you find the plaintiff's case is proved. If you do, you will say "Verdict for the plaintiff." If it is not proved you will say "Verdict for the defendant." If it is proved, then you will say "Verdict for the plaintiff" with such damages as you are satisfied resulted from what the defendant did to the plaintiff. If you would like to retire do so, and take any documents you like with you.

The FOREMAN of the JURY: My lord, cannot we have special terms?

Mr. JUSTICE DARLING: I have no power in the matter. I cannot order anything, but while you are out I will consider and see if anything can be done.

The Jury retired at 5.5 P.M., and returned into Court at 5.57 P.M.

The ASSOCIATE: Gentlemen, are you all agreed?

The FOREMAN of the JURY: Yes.

The ASSOCIATE: Do you find for the plaintiff or for the defendant?

The FOREMAN: We find for the plaintiff.

The ASSOCIATE: What damages?

The FOREMAN: £21.

The ASSOCIATE: £21.

The FOREMAN: 20 guineas; that is £21.

Sir EDWARD CLARKE: I ask your lordship for judgment for the plaintiff and a certificate for a special jury.

Mr. Justice DARLING: Yes. (*To the jury*): This is not a case in which I have any power to make an exceptional order. You have only served just your ordinary time. You will be discharged from serving again this week. You will get away two days earlier than you would have done.

Sir EDWARD CLARKE: I am told I ought to ask your lordship for an order for costs on the High Court scale.

Mr. Justice DARLING: Certainly. I have certified for a special jury. It is obviously a case for a special jury.

Sir EDWARD CLARKE: If your lordship pleases.

# THE METROPOLITAN WATER-SUPPLY.

*Report on Water Examinations for October, 1910.*

Dr. A. C. Houston, the Director of Water Examinations of the Metropolitan Water Board, has recently issued his report on the results of the chemical and bacteriological examinations of the London waters for the month ending Oct. 31st, 1910. This report shows that 1407 samples of water have been examined chemically or bacteriologically. Full details of the analyses are given in tables. The results of the analyses show that, speaking from chemical standards, the filtered waters have, generally speaking, maintained approximately their standard of purity, there being a slight deterioration only as regards the Lambeth and Southwark and Vauxhall supplies, and also as regards the Kempton Park and West Middlesex and Grand Junction supplies. The other filtered waters showed chemically a slight improvement. The bacteriological results were satisfactory and showed, on the whole, a slight improvement.

The value of the systematic and careful routine examinations which Dr. Houston is carrying out daily on the London waters cannot be too highly estimated. They are the best safeguard possible against any outbreak of water-borne disease in London, and in addition the results of these daily routine examinations must be of the greatest assistance to the engineers in charge of the filtration of the London waters at the various stations, since they form the only reliable check on the efficiency of the filtration processes.

*Results of the Storage of Water.*

Dr. Houston has recently published his sixth report on research work on "The Comparative Vitality of 'Uncultivated' and 'Cultivated' Typhoid Bacilli in Artificially Infected Samples of Raw River Water, with Special Reference to the question of Storage." This report is an exceedingly interesting and valuable contribution to our knowledge of the exact danger resulting from the possible infection of raw water with typhoid bacilli, and the results of Dr. Houston's investigations clearly indicate the manner in which the dangers from infection are best safeguarded. Dr. Houston deals in the first part of his report with the two varieties of typhoid bacilli which may be artificially experimented with—viz., "uncultivated" and "cultivated" bacilli. In the previous experiments made with typhoid bacilli "cultivated" bacilli were used which had been grown on agar cultures, and it might reasonably be argued that conclusions based on experiments with "cultivated" bacilli could not be applied to cases where the bacilli were uncultivated—i.e., taken fresh from a living patient. Professor E. J. McWeeney of Dublin has had under his care a patient whose urine was swarming with living typhoid bacilli, and Dr. Houston was, by the courtesy of Professor McWeeney, able to obtain from this patient living "uncultivated" typhoid bacilli for the carrying out of a valuable series of experiments detailed in his research report. The history of the case is given in detail, and it is of interest to note that the patient contracted typhoid fever as long ago as 1903 and was apparently completely cured after three months. Since that time the urine of the patient has contained swarms of typhoid bacilli, and apparently the patient has been the cause of infection of several cases of typhoid fever. On August 9th, 1910, Dr. Houston received 500 c.c. of the patient's urine and obtained from this by centrifugalisation great numbers of living typhoid bacilli. These were added to raw Thames river water, so that each cubic centimetre of water contained 770,000 organisms. The water was placed in a partially

filled stoppered bottle in a dark place. After one week only four living typhoid bacilli per cubic centimetre were present, and after 14 days it was found that no living typhoid bacilli remained in the water. Dr. Houston confirmed his scientific experiments by the practical one of drinking himself on the twenty-fourth day half a pint of the infected water with no harmful result. He states as his belief that, while the urine-polluted river water was grossly infective at the starting of the experiment, after 24 days it had become absolutely innocuous owing to the death of all the typhoid bacilli.

Dr. Houston made a second experiment of similar nature and found that at the end of one week no living typhoid bacilli remained in the water which had been grossly infected a week previously. On the twenty-third day and subsequently each day for four days Dr. Houston drank half a pint of the infected water with no harmful result to himself. He made comparable experiments with raw Thames water to which "cultivated" typhoid bacilli had been added. It was found that the cultivated organisms were more resistant to the effects of storage, and some living bacilli were found after five weeks' storage. The fact that the uncultivated typhoid bacilli die much more speedily in raw river water than their cultivated brethren is of far-reaching practical importance, and very reassuring, since the danger of drinking polluted water arises only from the possible presence of the "uncultivated" bacilli.

The conclusions of Dr. Houston's experiments go to further support what he has continually insisted upon in so many of his previous reports—viz., that adequate storage of raw water antecedent to filtration is the best possible safeguard against water-borne epidemic diseases, and that an adequately stored water is to be regarded as a "safe" water. Dr. Houston hopes that the day is not far distant when adequate storage of the whole of the London waters will be secured. At present this does not appear to be the case, though great improvements have recently been made in this respect.

In Addendum C, Dr. Houston gives the results of the examination of the pre-filtration water—i.e., representative samples of practically all the London water antecedent to filtration. The experiments on which the results are based were made on examinations of the water for the bacillus coli. Dr. Houston, from his investigations, has made some very valuable suggestions as regards weak points in the system of supply which might, without much difficulty, be remedied. No doubt these suggestions will be adopted at as early a date as possible.

In Addendum D an extremely interesting account is given of the subject of typhoid carriers. Unfortunately there is no legal provision enabling the carrier to be debarred from undertaking what occupation he pleases, notwithstanding the fact that a carrier who is engaged in the milk trade or in the preparation or handling of food may be a public danger.

The whole of this sixth research report is teeming with interest, and Dr. Houston is to be congratulated on a valuable and courageous addition to his previous excellent researches.

## THE HEALTH OF THE ARMY IN 1909.

### II.[1]

#### *Sanitation.*

MUCH attention is now being paid to the instruction of regimental officers and men in army sanitation. Over 400 officers were instructed and examined before promotion to captain, nearly all of whom passed the test successfully. The army school of sanitation at Aldershot is vigorously at work, regimental and medical officers and men, and members of the Officers Training Corps and the Territorial Force receiving instruction by lectures and demonstrations. At this institution, also, valuable experimental investigations have been carried on during the year in the direction of improving the filter water-cart and the exchange heater apparatuses in use for purifying water. The Griffith machine continues to be favourably spoken of. A new feature has been introduced by the utilisation of the steam generated in the sterilising process (that was formerly allowed to go to waste), as a means of filling the supply tanks, thus saving the labour of pumping.

The sanitary condition of *Camps* is reported generally to have been good; greater attention is being paid by all ranks to sanitary affairs; it is stated that the importance of sanitation is, perhaps, not sufficiently recognised by members of the Territorial Force, a circumstance, no doubt, due to the shortness of their period of training which hardly leaves sufficient time for its study. Large bodies of men, both Regulars and Territorials, have been encamped during the training season on very limited areas without any serious outbreak of disease; on Salisbury Plain over 80,000 troops were under canvas during the summer. At Caerwys, in Flintshire, the camp between August 1st and 15th, comprising roughly 14,000 men, "perhaps represents the largest body of Territorial troops ever brought together in a single encampment for so long a period. The camp was certainly unique in the fact that the water-supply had been condemned, and all water used for drinking purposes was sterilised by means of heat exchange apparatus." This speaks very well for the sanitary supervision of the camp; we hope, however, that it will not become a routine practice to mass many thousands together—chiefly untrained troops—on sites where the water-supply is unfit for drinking.

A change has been made in the source of lymph-supply for *Vaccination*. Formerly it was prepared at the Army Vaccine Institute at Aldershot; since September, 1909, it has been supplied from the Government Lymph Establishment at Hendon. Of the recruits enlisted 949 per 1000 had vaccination marks, and 0·4 per 1000 marks of small-pox. The proportion per 1000 bearing no marks either of small-pox or vaccination was 50·6. This shows a higher proportion of unprotected persons than has hitherto been noted. In the five years, 1891–95, the average was 27·7; in 1896–1900, it was 34; in 1901–05 it reached 39·3, in one year only (1903) having been above 40; in the last four years, 1906–09, the ratios have been 35·9, 42·8, 49·9, and 50·6. The matter is of little consequence for the army, because every recruit that needs it is either vaccinated or re-vaccinated. But if these figures are to be taken as generally applicable to the young adult male population, they indicate that a large amount of inflammable material is accumulating throughout the country.

#### *Infectious Diseases.*

It is stated on page 36 that "cases of infectious disease were much more numerous among the troops than in the previous year, due chiefly to excessive prevalence of scarlet fever and measles at certain large stations." This is not borne out by the figures in the tables, which show that for the acute specific fevers in Group A there were 2976 admissions in 1909, compared with 4460 in 1908. There were rather more cases of diphtheria and scarlet fever, but fewer cases of enteric fever and measles, and a large reduction in the admissions for influenza, 2032 compared with 3449 in 1908. None of the outbreaks appear to have been serious. The only real epidemic of enteric fever occurred at Kilworth Camp, in the Cork district, where 24 cases were admitted; the milk-supply came under suspicion and infection was traced to the presence of a female carrier on the farm whence the milk was derived; she had had an attack of enteric fever in 1903, and her subsequent movements had been followed for some time by the appearance of febrile attacks among those with whom she had come in contact, either directly or through the medium of the milk-supply. The outbreak was chiefly connected with the officer's messes, 14 officers and 9 servants being attacked. On examination the girl's blood was found to react with B. typhosus up to a dilution of 1 in 100, and the urine contained typical enteric bacilli. The milk used at the messes was said to have been boiled, but obviously this was not invariably the case.

#### *Barracks.*

Extensive improvements are being carried out in the housing of troops; some barracks, as at Dorchester and Newbridge, have been vacated, and others will be vacated shortly. The most important new works in hand are the Redford Barracks, near Edinburgh; new married quarters are being constructed at several stations.

[1] No. I. was published in THE LANCET of Feb. 25th, 1911, p. 534.

*The Mediterranean Area.*

The stations in the Mediterranean Command are Gibraltar, Malta, Crete, Cyprus, and Egypt. All these stations show a reduction in the admission-rate, except Gibraltar; all except Crete have a lower death-rate; and all without exception have a lower ratio constantly sick than in the previous five-year period. Gibraltar and Malta have the lowest admission rates (370·3 and 373·6 respectively), Egypt has the highest (672·9); the death-rates were 2·46 at Gibraltar, 2·97 in Malta, and 4·21 in Egypt. The average strength of the command was 15,948.

At *Gibraltar* no serious illness occurred, except an outbreak of 14 cases of Malta fever. There had been no incidence of the disease in the garrison since two isolated cases in 1907; the civil returns also showed not a single case in 1908, but in May, 1909, there were two cases among the civil inhabitants. Some admissions for fever occurred in the garrison in spring and early summer which were thought to be influenza; and in July the discovery of Phlebotomus pappatasii[2] on the Rock caused attention to be given to phlebotomus fever due to the sand-fly; some of these early cases may have been Malta fever, but the sanitary officer, Major C. E. P. Fowler, thinks this very doubtful. In September 11 cases were admitted from the military population, of a severe type, the infection being a mixed one with both M. melitensis and B. typhosus. The infection was, there is little doubt, derived from a herd of goats, some of which had been landed from Malta in April; these animals had a clean bill of health from Malta, but Major Fowler obtained a positive reaction for M. melitensis in two on arrival, and subsequently in four others; 13 out of the 14 Malta fever patients had been consuming milk from the dairy to which these goats belonged. "The fact, or coincidence, is mentioned for what it is worth. Proof would be impossible of attainment" To most people the sequence of occurrences would afford sufficient grounds for forming an opinion; but the curious point is that amongst the Gibraltar goats, numbering 300 or 400 (whose blood reaction is noted twice a year), a number of positive results has always been obtained, varying from 10 to 15 per cent., showing that this proportion of animals was possibly infected with M. melitensis, and yet no case occurred among the consumers of the milk until the arrival of the imported goats from Malta. Six cases of enteric fever were reported, all sporadic.

*Malta.*—The improvement in health of the troops at this station still continues; as compared with the previous quinquennial average, 1904 to 1908, the ratios for admission to hospital and men constantly sick have fallen from 540·8 and 35·54 to 373·6 and 24·47; the death-rate is 2·97 compared with 4·97. For the ten-year period, 1896–1905, the admissions averaged 748·2 per 1000, the constantly sick 47·78, and the deaths 7·44. Since the beginning of 1907 there have been practically no admissions for Malta fever; the reductions have been in influenza, some forms of venereal disease, and generally all round. The number of invalids sent home was higher than in 1908, owing to the large number of cases of tubercle of lung (17) and of heart disease (13). Enteric fever, unfortunately, shows an increase this year, 14 cases having been admitted. The outbreak coincided with a marked increase among the civil population. It is stated that none of the cases were attributable to insanitary conditions in barracks; five of them, however, came from Fort Manoel, where dry earth latrines are in use and flies abundant. They were believed to be connected with the arrival of a carrier case from India. The substitution of saponified cresol for dry earth in latrines might surely be carried out in Malta now that its efficacy has been demonstrated in India. Pyrexia of uncertain origin caused 235 admissions, a ratio of 44·6 per 1000, compared with 102·9 for the quinquennium. The cases were investigated by Lieutenant-Colonel C. Birt, who believes the disease to be identical with the pappataci fever of Dalmatia, infection being conveyed by means of Phlebotomus pappatasii. The fever is of two to five days' duration and not of a serious character. It was distributed all over the island, except at Imtarfa, near Citta Vecchia, which stands at 630 feet above the sea. There is a distinct relation between prevalence of the disease and the distribution of the sand-fly, and transmission by this means has been actually proved; the fly remains virulent for seven to ten days; no pathogenic organism has yet been identified. One case of Malta fever occurred in the garrison; the patient had drunk unboiled goat's milk in a restaurant in Valetta. Improvement has been effected in the sewerage arrangements, especially in the way of increased flushing; a large tank for storage of sea water is in course of construction on Kemmana Hill, which when finished will supply flushing water in ample quantity for the whole island. When Malta fever is abolished, or, rather, now that it has been abolished, and when the closets and sewers of the island are properly flushed, Malta will regain much of its old popularity as a delightful winter resort.

The small garrisons in *Crete* and *Cyprus* had good health during 1909, the constantly sick ratio being only 25·52 per 1000 in Crete and 16·54 in Cyprus. Two types of pyrexia prevailed in Crete, one resembling the pappataci fever, and lasting from one to three days; the other, of longer duration, from seven to ten days, and with more marked symptoms. Malaria diminished in Crete owing to vigorous anti-mosquito operations.

*Egypt.*—With an average strength of 5457, the admissions to hospital were 672·9, and the constantly sick 40·61 per 1000; the deaths were 4·21 per 1000. These ratios are all lower than those for the preceding quinquennium. Dysentery, pyrexia, pneumonia, and tonsillitis caused more admissions than the average; enteric fever and malaria were less prevalent, also venereal diseases. Nine cases of small-pox occurred in Cairo, one being hæmorrhagic and confluent, terminating fatally; the condition of this man as regards vaccination marks and history is not stated. There were 21 cases of enteric fever, mostly from the Abbassiyeh barracks, Cairo; three of these cases had been inoculated. It has to be admitted that it is very difficult to trace enteric fever to any single, or definite, source in Cairo; there are so many likely causes. It is noted that there was a plague of common house-flies in the spring, and again from September to the end of the year; but there was practically no enteric fever when the fly plague was worst. The water-supply is good at its origin, from the wells at Zeitoun and Rod-el-Farag, but the mains are laid in filth-sodden ground, and if they are not perfectly in order infection might easily gain access. Pasteur filters are in use in barracks. The milk-supply for the troops is entirely tinned; for officers' messes it is said to be invariably boiled. Possibly the disease is contracted outside barracks. Pyrexia of uncertain origin caused 431 admissions (79 per 1000), a considerable increase on the quinquennial ratio of 59·5 per 1000. A careful description is given of the cases, which are considered to belong to four or five different diseases. The phlebotomus is the common sand-fly of Cairo, and it is here that the fever appears to be endemic. It is noted that the rise and fall of the disease coincide with the rise and fall of the Nile and of the summer temperature. Possibly variable types of influenza and dengue are included under the same heading. The principal increase in 1909 occurred in the citadel at Cairo, and it is suggested that aggregation of cases in the hospital may have had something to do with this. The only point that seems to stand out quite clearly is that the disease exists definitely in Cairo and hardly at all at Alexandria. No deaths resulted, and the average number constantly sick was only 1·77 per 1000. It would seem, however, that here is an opportunity for a careful and detailed investigation by a skilled officer specially deputed for the purpose. A good deal of sanitary work has been carried out during the year; new infantry barracks have been commenced at Cairo; water-tanks have been protected against mosquitoes; Berkefeld filters have been installed throughout barracks, and the water is no longer boiled; the pressure of water is not sufficient to enable Chamberland filters to be used. At Alexandria the public water-supply, which is derived from a very foul source, the Mahmoudiyeh Canal, is treated on the Jewell system of filtration, and in barracks all drinking water is in addition passed through Chamberland or Berkefeld filters. Latrines and urinals are treated most successfully with cresol solution; there is no unpleasant smell, and flies are conspicuous by their absence.

*(To be continued.)*

[2] The spelling of this word is uncertain. It is spelt differently in different parts of the report. In a recent number of the R.A.M.C. Journal Lieutenant-Colonel Cecil Birt spells the name of the fly, P. pappatasii, which appears to us preferable. The original form seems to have been "pappatacifieber."—ED. L.

# MEDICINE IN THE ENCYCLOPÆDIA BRITANNICA.[1]

## II.—PURE MEDICINE.

WE proceed to review briefly some of the more important articles on general medical subjects, dealing in this note with the volumes from A to I.

The subject of Aphasia is discussed clearly and succinctly in an article of about two and a half columns in length. The views of Pierre Marie in opposition to current teaching on the subject are briefly mentioned in a footnote. The various meanings attaching to the word "catarrh," as applied to the effects of conditions of irritation of the respiratory and other mucous membranes, are described, though it is perhaps not made clear that an inflammatory reaction is the basis of catarrhal states. Catalepsy and its associations are described and referred to the class of functional nervous disorders, but this condition is also mentioned as occurring in association with epilepsy and grave forms of mental disease. Cramp is described as a painful spasmodic contraction of muscles. In addition to the common form of cramp in the limbs, which is stated to be associated frequently with a rheumatic or gouty tendency, other forms of muscular spasm are mentioned, including writer's cramp. Gastralgia is referred to as cramp of the stomach, which seems to us to apply too definite a pathology to this somewhat vague condition. The article on Cretinism describes the appearance of the cretin and differentiates this disease from Mongolism, achondroplasia, and infantilism. The use of thyroid extract in treatment is discussed. It would have been an advantage to indicate that the secretion of the thyroid gland, to the absence or deficiency of which the disease is attributed, is an internal secretion, in view of the fact that this work is intended for non-medical as well as professional readers.

The Pathology of the Digestive Organs is reviewed in a long article, in which the various general diseases and abnormalities of structure and function are enumerated and briefly described. In dealing with appendicitis, it is stated that it appears to be increasing in frequency, and that it is associated by many with the modern deterioration in the teeth. The former of these statements is probably correct, but the latter is open to question. Perityphlitis is mentioned as a separate condition with very similar symptomatology, and is regarded as "doubtless in former days frequently due to the appendix, an acute or chronic inflammation of the walls of the cæcum often leading to abscess formation outside the gut, with or without direct communication with the canal." This somewhat vague description is misleading, and the term perityphlitis might with advantage be dropped, since it is a relic of an erroneous interpretation of appendicular disease. In connexion with diseases of the colon, membranous colitis is described as a very severe inflammation, whereas from the description it is evident that under this heading the condition of mucous colic is included, the inflammatory factor in which is now regarded as doubtful, or at any rate subsidiary. In connexion with the subject of tuberculous abdominal disease the statement that "it is hardly possible that tubercular invasion of the mesenteric glands can ever occur unaccompanied by peritoneal infection" is certainly not in accordance with recent researches, which have clearly demonstrated that such an invasion may occur, even without any discoverable lesion in the intestinal mucous membrane. In other respects the article gives a useful *résumé* of the pathology of diseases of the digestive organs.

Diuretics are described and classified according to their mode of action. The article on Diphtheria is an admirable account of the main facts regarding this disease, its causation and treatment, and contains also a critical examination of some of the more important problems connected with its epidemiology. The conditions governing the general prevalence of diphtheria and its epidemic rise and fall are described; and the hypotheses which have been put forward to explain them, notably that of Dr. A. Newsholme, that diphtheria only becomes epidemic in years when the rainfall is deficient, are critically considered. The origin and use of antitoxin are well described and the results of its employment convincingly demonstrated. The article on Dysentery is also clearly and carefully written. The two varieties, amœbic and bacillary, are differentiated from one another, and the distinctions between the Shiga and Flexner strains of organisms in the bacillary form are brought out. The treatment is also discussed, and measures for prevention are enumerated. The subject of Dyspepsia is described in general and somewhat popular fashion, but useful advice is given in regard to treatment, notably in connexion with the quantity and nature of the food taken, the necessity for careful and efficient mastication, and the value of moderation and regularity.

Dreams are discussed in an interesting article, which also gives an account of the explanations that have been offered of their occurrence, including the views of classical and mediæval philosophers. Hallucination receives very detailed consideration in an article of no little interest. It is first defined and distinguished from illusion, then a classification is given, and the conditions under which hallucinations may occur, both in health and disease, are examined. The nature of the nervous processes underlying hallucination and the theories put forward by various psychologists are critically discussed. An interesting analysis is given of the evidence concerning so-called coincidental hallucinations—i.e., apparitions of persons known to be in distant places, more especially at or near the time of death. The results of the census of hallucinations made by the Society for Psychical Research are quoted. Hypochondriasis is defined in a short note about half a column in length, its symptoms and associations being outlined carefully. In the article on Hysteria the well-known definition of Möbius is quoted—viz., that it is "a state in which ideas control the body and produce morbid changes in its functions." The general and local manifestations of hysteria are very briefly stated. The fact that a hysterical attack may occur as an immediate sequel to an epileptic fit is mentioned, and a warning is given that in cases of petit mal the post-epileptic character of the hysterical symptoms is likely to be overlooked. Treatment is dismissed with but little notice, but the important distinction between hysteria and malingering is insisted upon.

A short but interesting note on Hydropathy contains a historical account of its development as a formal system of treatment and affords a summary of the various methods of applying water therapeutically which have been employed. The article on Hydrophobia deserves special commendation. It gives an admirable account of the disease as it occurs in dogs, and then a description of its characters in the human subject. The two forms in dogs—the furious and the dumb—are described in full detail, various stages being differentiated. A clear and intelligible account of the Pasteur treatment is given, and it is rightly pointed out that it is to be regarded as an anticipatory cure, since it is not exactly a treatment, being useless or nearly so when the disease is well established. Reference is also made to the recent attempts at actual treatment by means of antirabic serum by Babes and Lepp and by Tizzoni and Centanni. The value of the muzzling order as a means of eradicating the disease is discussed, and due tribute is paid to Mr. Walter Long, the Minister who so successfully enforced that order in this country. An interesting presentation of the chief facts regarding Hypnotism is contained in the article devoted to that subject. After a brief historical account of the chief discoveries in connexion with hypnotic states, the effects of suggestion are described and post-hypnotic results are considered. The theory of mental dissociation is carefully enunciated and its merits are pointed out. This theory regards hypnosis as a state of relative dissociation and assumes "a temporary functional depression of all or of many of the associations or nervous links between the neural dispositions." The medical applications of hypnotism and its possible dangers are discussed.

Influenza forms the subject of an interesting article in which the origin and spread of the disease are discussed as well as its symptomatology and treatment. The evidence that the dissemination of influenza occurs by human agency, and not, as was formerly supposed, by atmospheric influences, is given, and suggestions are offered with a view to lessening the spread of the disease in epidemics. The subject of Insanity forms the basis of a long article, containing a valuable and practical account of the ordinary forms of mental alienation, both

[1] Article I. was published in THE LANCET of Feb. 25th, 1911, p. 530.

congenital and acquired. The causes of insanity are enumerated. The various forms of idiocy, imbecility, and insanity are classified and described. The classifications given are practical and satisfactory. The legal aspects of insanity are also considered at some length. The treatment is discussed in a special section of the article, giving suggestions for the best methods of carrying out treatment sympathetically and effectively. Hospitals for the acutely insane, with outdoor departments for advice and diagnosis of early cases, and colonies for the chronic insane patients are recommended. From the above brief notes it will be gathered that the medical writers for the Encyclopædia Britannica have realised well their responsibilities, and on the whole have also performed the difficult task of writing on highly technical subjects in such a way as to be informatory to the general public while preserving a position of scientific authority. The pure medicine in the remaining volumes of the issue, containing as they do the inclusive article on Medicine, will be considered later.

# Looking Back.

## THE LANCET, *SATURDAY*, March 2nd, 1833.

### ST. THOMAS'S HOSPITAL.

#### GLANDERS IN THE HUMAN SUBJECT.

"A new disease is opened to us" said some of the medical officers of this hospital, after examining the body of one of Dr. Williams's patients on Monday, February the 18th, in the dead-house. Drs. Williams, Elliotson, Roots, and Bright, and Mr. Travers and Mr. Youatt (London University), with several other professional gentlemen and a crowd of students, were present on this occasion. The corpse was that of a man, who had been admitted ten days or a fortnight before, for we hardly know what, nor could learn. The case progressed up to Thursday the 14th, when a symptom appeared which Dr. Williams supposed to be "gout in the head." The attention of Dr. Elliotson was soon after called to the man, who, when seen by that gentleman, presented the following diseased characters. Several large phlyzaceous pustules appeared on the face and neck; a profuse stinking discharge issued from each nostril; there was swelling and bright redness of the eyelids, so as to close the eyes, and gangrenous inflammation of the right temple and adjoining part of the nose; soft fluctuating swellings, some red, some livid, some pinkish arose in the upper and lower extremities, and one of great size was on the head. His age was 23, but he appeared to be 40.

"This man has glanders," observed Dr. Elliotson, immediately; "have you ever been in a stable, my man?"—"Yes, Sir, I have been in stables all my life."—"Have you had anything to do with glandered horses?"—"Oh, yes, Sir, master had a glandered horse twelve months ago."—"And did any of the snivel ever fall upon any part of your body?"—"Yes, Sir, I have had my hand covered with it."

The man then said, "Oh, then I've got the glanders, and I shall die, but so happy, because I die through the horses, and I know what I've got." There was a scar on his right hand. He eventually became delirious, and was obliged at last to be strapped down; and a short time before he died, kept calling out, during an hour or more, "Stop that horse! stop that horse."

The inspection of the body, which was opened by Mr. Rush, excited great interest. Dr. Elliotson entered the dead-house under the certain expectation, that the result would tend to establish the position so indisputably urged in his paper, in the 16th volume of the *Medico-Chirurgical Transactions*, and verified in several instances in this journal, that glanders was communicable from the horse to man.* Dr. Williams did not entertain the same impression, either not crediting, or appearing not to be aware of, the facts on record tending to establish the fact of the occurrence of this disease in man. Neither did Mr. Travers appear to have made up his mind in the affirmative of the question. Before leaving the place of autopsy, however, no doubt on the subject seemed to exist in the breasts of either of the gentlemen present. Mr. Youatt (the lecturer on veterinary medicine) attended, on invitation, to witness the inspection; and to this gentleman reference was made for his opinion on each peculiar morbid appearance. The representations of Mr. Youatt tended in most instances to confirm the views entertained by Dr. Elliotson, and also, apparently with equal conviction, by Dr. Roots, with regard to the case. The ulcerations did not all present an equally glanderous aspect; but in most of them, especially in one found in the trachea, Mr. Youatt observed, that it presented just such an appearance as he should have expected to find in the horse—rather shallower however in the man than in the brute. He called it a true glanderous chancre. The frontal sinus was filled with discharge, and the membrane of the septum was ulcerated, and presented exactly the appearance seen in that part of glandered horses. At the bottom of the suppurations and in the schneiderian membrane, several such granules were found as appear in the horse in the early stage of the disease, and the existence of which granules has caused the French to call it the "tubercular disease."

The case, in short, so precisely agrees with all the other published cases of alleged glanders in the human subject, that not a doubt can reasonably be entertained on the matter.

(Here follow, in the original, four columns entitled "Mr. Youatt's Report of the above Case." We have not transcribed them for lack of space.)

* A case, if we mistake not, is also on record in some of the old Journals, which has not subsequently been quoted, where a great kitchen knife, which had been employed in skinning a glandered horse, was afterwards used by a cook, who accidentally cut himself with it, and died in a short time with all the symptoms of glanders.—REP. L. March 2, 1833.

## VITAL STATISTICS.

#### HEALTH OF ENGLISH TOWNS.

IN 77 of the largest English towns 7526 births and 5345 deaths were registered during the week ending Feb. 25th. The annual rate of mortality in these towns, which had been equal to 16·0, 17·6, and 17·2 per 1000 in the three preceding weeks, declined to 16·2 in the week under notice, and was equal to the average annual death-rate recorded in these towns and also in London during the first eight weeks of the current quarter. The annual death-rates in the 77 towns during last week ranged from 7·0 in Bury, 7·7 in Hornsey, 8·3 in King's Norton, and 8·4 in Handsworth (Staffs), to 21·3 in St. Helens, 21·9 in Wigan, 22·0 in Stoke-on-Trent, and 25·9 in Middlesbrough. The 5345 deaths from all causes in the 77 towns showed a decline of 328 from the number returned in the previous week, and included 601 which were referred to the principal epidemic diseases, against 477, 525, and 621 in the three preceding weeks; of these 601 deaths, 359 resulted from measles, 91 from whooping-cough, 53 (of infants under two years of age) from diarrhœa, 51 from diphtheria, 33 from scarlet fever, and 14 from enteric fever, but not one from small-pox. The fatal cases of measles, which had steadily increased from 160 to 333 during the first seven weeks of the current year, further rose last week to 359, and caused the highest annual rates of 2·5 in Coventry, 2·6 in West Ham, 4·2 in Aston Manor, 5·4 in Devonport, and 7·5 in Sheffield. The deaths from whooping-cough, which had increased from 85 to 132 in the five preceding weeks, declined last week to 91; the highest death-rates from this disease were 1·2 in Willesden, in Reading, and in Norwich, 1·4 in Middlesbrough, and 1·5 in Bootle. The 53 deaths of infants under two years of age attributed to diarrhœa showed a decline of 11 from the number recorded in the previous week. The fatal cases of diphtheria, which had been 58 and 55 in the two preceding weeks, further declined last week to 51, and included 11 in London, 7 in Leeds, 5 in Manchester, 4 in Portsmouth, and 3 in Blackburn. The deaths referred to scarlet fever, which had been 21 in each of the three preceding weeks, rose to 33 last week; 6 deaths were registered in London, 5 in Liverpool, 3 in Manchester, and 2 each in Stoke-on-Trent, in Blackburn, and in Sheffield. The 14 fatal cases of enteric fever showed a decline of 2 from the number recorded in the previous week, and included 4 in London and its suburban districts. The number of scarlet fever patients under treatment in

the Metropolitan Asylums and the London Fever Hospital, which had been 1264, 1257, and 1276 in the three preceding weeks, declined to 1242 on Saturday last; 138 new cases of this disease were admitted to these hospitals during last week, against 130, 147, and 166 in the three preceding weeks. These hospitals also contained on Saturday last 906 cases of diphtheria, 586 of measles, 195 of whooping-cough, and 44 of enteric fever; in addition to these 35 cases of small-pox were admitted to the small-pox hospitals of the Metropolitan Asylums Board during last week. The 1540 deaths from all causes in London last week (showing a decline of 73 from the number in the previous week) included 395 which were referred to diseases of the respiratory system, against 365, 404, and 421 in the three preceding weeks. In the 77 towns 173 deaths resulted from different forms of violence, against 187 and 163 in the two preceding weeks, and 391 inquest cases were registered. The causes of 36, or 0·7 per cent., of the deaths registered during the week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in London and its eight suburban districts, in Manchester, Leeds, Bristol, Bradford, Newcastle-on-Tyne, Nottingham, Salford, and in 42 other smaller towns; the 36 uncertified causes of death in the 77 towns last week included 11 in Liverpool, 3 in Stoke-on-Trent, 3 in Birmingham, and 2 each in St. Helens, Rochdale, and Sunderland.

### HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns 888 births and 641 deaths were registered during the week ending Feb. 25th. The annual rate of mortality in these towns, which had been 18·2, 19·8, and 19·0 per 1000 in the three preceding weeks, declined again to 17·4 in the week under notice. During the first eight weeks of the current quarter the death-rate in these towns averaged 17·0 per 1000, and was 0·8 above the mean rate during the same period in the 77 English towns. The annual death-rates last week in the eight Scotch towns ranged from 14·6 and 15·4 in Aberdeen and Edinburgh to 20·8 in Perth and 25·0 in Dundee. The deaths from all causes in the eight towns last week showed a decrease of 57 from the number returned in the previous week, and included 76 which were referred to the principal epidemic diseases, against 63, 69, and 68 in the three previous weeks; these 76 deaths were equal to an annual rate of 2·1 per 1000, the highest epidemic rates being 4·2 in Perth and 5·9 in Leith. Of these 76 deaths from the principal epidemic diseases, 39 resulted from whooping-cough, 12 from diarrhœa, 9 from diphtheria, 8 from scarlet fever, 6 from measles, and 2 from enteric fever, but not one from small-pox. The fatal cases of whooping-cough, which had increased from 14 to 45 in the four preceding weeks, declined to 39 last week, of which 22 occurred in Glasgow, 8 in Leith, 5 in Dundee, and 3 in Edinburgh. The 12 deaths attributed to diarrhœa showed an increase of 3 upon the number returned in the previous week, and included 8 of infants under two years of age. The deaths from diphtheria, which had been 11 and 7 in the two preceding weeks, rose to 9 last week; 3 deaths were recorded in Glasgow and 2 in Edinburgh. The 8 fatal cases of scarlet fever showed an increase of 7 upon the number in the previous week, and included 4 deaths in Glasgow. The 6 deaths from measles showed a slight increase upon recent weekly numbers; 5 deaths were registered in Edinburgh. The 2 fatal cases of enteric fever occurred in Glasgow. The deaths in the eight towns referred to diseases of the respiratory system, which had increased from 117 to 181 in the four preceding weeks, declined last week to 139, but were 42 above the number returned in the corresponding week of last year. The deaths resulting from different forms of violence, which had been 28 and 22 in the two preceding weeks, further declined last week to 21. Of the 641 deaths from all causes in the eight towns last week, 180, or 28 per cent., occurred in public institutions. The causes of 25, or 3·9 per cent., of the total deaths were not certified or not stated; in the 77 towns last week the proportion of uncertified causes of death did not exceed 0·7 per cent.

### HEALTH OF IRISH TOWNS.

In the 22 town districts of Ireland, having an estimated population of 1,163,596 persons, 596 births and 466 deaths were registered during the week ending Feb. 25th. The annual rate of mortality in these towns, which had been 19·6, 24·1, and 22·7 per 1000 in the three preceding weeks, declined again last week to 20·9, and was equal to the average annual rate recorded in these towns during the first eight weeks of the current quarter. During the same period the death-rate in the 77 largest English towns did not exceed 16·2 per 1000, and in the eight principal Scotch towns it was equal to 17·0 per 1000. The annual death-rate last week was equal to 23·8 in Dublin, 18·5 in Belfast, 24·7 in Cork, 22·6 in Londonderry, 9·6 in Limerick, and 13·6 in Waterford; in the 16 smallest of the Irish town districts the annual death-rate last week averaged 21·6 per 1000. The 466 deaths from all causes in the 22 town districts last week showed a decrease of 41 upon the number returned in the previous week, and included 25 which were referred to the principal epidemic diseases, against 26 and 29 in the two previous weeks; these 25 deaths were equal to an annual rate of 1·1 per 1000, the highest epidemic rates being 2·6 in Dublin and 4·8 in Sligo. Of these 25 deaths from the principal epidemic diseases, 10 resulted from whooping-cough, 5 from diarrhœa, 3 from measles, 3 from scarlet fever, 2 from diphtheria, and 2 from enteric fever, but not one from small-pox. The deaths from whooping-cough, which had been 9, 8, and 11 in the three preceding weeks, were 10 last week, and included 7 in Dublin. The 5 deaths from diarrhœa included 3 of infants under two years of age; 4 other deaths at this age were referred to enteritis. Of the 3 deaths from scarlet fever, 2 occurred in Dublin. The 3 fatal cases of measles, 2 of enteric fever, and 2 of diphtheria were all recorded in Dublin. The deaths in the 22 towns referred to diseases of the respiratory system, which had been 141 and 137 in the two preceding weeks, declined to 110 in the week under notice. The 466 deaths from all causes last week included 127, or 27 per cent., which occurred in public institutions. The causes of 12, or 2·6 per cent., of the deaths in the 22 towns last week were not certified either by a registered medical practitioner or by a coroner after inquest; the proportion of uncertified causes last week did not exceed 0·7 per cent. in the 77 English towns, but was equal to 3·9 per cent. in the principal Scotch towns.

### VITAL STATISTICS OF LONDON DURING JANUARY, 1911.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 4·1 per 1000 of the population, provisionally estimated at 4,912,054 persons in the middle of this year. In the three preceding months the rates were 5·9, 5·0, and 4·3 per 1000 respectively. The lowest rates last month were recorded in Paddington, Kensington, Chelsea, the City of Westminster, Hampstead, and Holborn; and the highest rates in Stoke Newington, Finsbury, Bethnal Green, Bermondsey, and Battersea. Scarlet fever continued to show a declining prevalence last month; among the several metropolitan boroughs the greatest proportional prevalence of this disease was recorded in St. Pancras, Stoke Newington, Battersea, Wandsworth, and Woolwich. The Metropolitan Asylums Hospitals contained 1280 scarlet fever patients at the end of last month, against 1825, 1727, and 1574 at the end of the three preceding months; the weekly admissions averaged 130, against 229, 183, and 155 in the three preceding months. Diphtheria was more prevalent than it had been in the preceding month; this disease was proportionally most prevalent last month in Hammersmith, Islington, Stoke Newington, the City of London, and Bermondsey. There were 842 diphtheria patients under treatment in the Metropolitan Asylums Hospitals at the end of last month, against 866 and 827 at the end of the two preceding months; the weekly admissions averaged 107, against 106 and 95 in the two preceding months. The prevalence of enteric fever showed a considerable decline from that recorded in other recent months; the greatest proportional prevalence of this disease was recorded in Finsbury, Bethnal Green, Poplar, Bermondsey, and Lewisham. The number of enteric fever

* Including membranous croup.

† The death-rates are corrected for variations in sex- and age-constitution of the populations of the several boroughs, the population of England and Wales being taken as the standard.

patients under treatment in the Metropolitan Asylums Hospitals, which had been 134 and 88 at the end of the two preceding months, had further declined to 68 at the end of last month; the weekly admissions averaged 7, against 16 and 11 in the two preceding months. Erysipelas was proportionally most prevalent in Finsbury, Bethnal Green, Stepney, Bermondsey, and Camberwell. The 22 cases of puerperal fever notified during the month included 4 in Fulham, 3 in Stepney, and 2 each in the City of Westminster, Hampstead, and Lewisham. Of the 2 cases notified as cerebro-spinal meningitis, 1 belonged to Islington and 1 to Bethnal Green.

The mortality statistics in the table relate to the deaths of persons actually belonging to the several boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased persons had previously resided; the death-rates are further corrected for variations in the sex and age constitution of the several boroughs. During the four weeks ending Jan. 28th the deaths of 5915 London residents were registered, equal to a corrected annual death-rate of 16·5 per 1000, against 17 4 and 15 8 in the two preceding months. The death-rates last month ranged from 10·4 in Greenwich, 10·6 in Hampstead, 11·8 in Wandsworth, 12·7 in the City of Westminster, 13·1 in Fulham, and 13·3 in Lewisham, to 20·5 in Southwark, 20·8 in Hammersmith, 21·7 in Bermondsey, 22·0 in Shoreditch, and 24·1 in Finsbury and in the City of London. The 5915 deaths from all causes included 322 which were referred to measles, 14 to scarlet fever, 55 to diphtheria, 104 to whooping-cough, 18 to enteric fever, and 71 (among children under two years of age) to diarrhœa and enteritis. The lowest death-rates from these diseases in the aggregate were recorded in Chelsea, the City of Westminster, Hampstead, Deptford, and Greenwich; and the highest rates in Kensington, Hammersmith, Finsbury, Bermondsey, and Battersea. The 322 deaths from measles were equal to the number recorded in the previous four weeks, but were nearly double the corrected average number for the first four weeks of the years 1906–10; the highest death-rates from measles last month occurred in Kensington, St. Marylebone, Finsbury, Bermondsey, and Battersea. The 14 fatal cases of scarlet fever were equal to only one-third of the corrected average number; of these 14 deaths, 2 belonged to Hackney, 2 to Lambeth, 2 to Camberwell, and 2 to Lewisham. The 55 fatal cases of diphtheria were 13 fewer than the corrected average number; this disease was proportionally most fatal in Hammersmith, Fulham, Finsbury, Poplar, and Battersea. The 104 deaths from whooping-cough were 11 below the corrected average number; this disease showed the greatest proportional mortality in St. Pancras, Finsbury, Bethnal Green, and Battersea. The 18 fatal cases of enteric fever were slightly above the corrected average number, and included 3 in Stepney, 3 in Lambeth, 2 in Islington, 2 in Poplar, and 2 in Bermondsey. The 71 deaths from diarrhœa and enteritis among children under two years of age included 7 in Islington and in Battersea, 6 in Lambeth, and 5 each in Paddington, Bethnal Green, Stepney, Southwark, and Wandsworth. In conclusion, it may be stated that the aggregate mortality in London from the principal infectious diseases (excluding diarrhœa) was 26 per cent. above the average.

## THE SERVICES.

### ROYAL ARMY MEDICAL CORPS.

THE undermentioned Lieutenants to be Captains (dated Jan. 29th, 1911):—George F. Dawson, Thomas McC. Phillips, Harry V. B. Byatt, Harold S. Dickson, Ronald E. Todd, Gerard Petit, Forbes J. Stuart, John B. Hanafin, Harold Gibson, William R. O'Farrell, John A. Renshaw, Cecil A. T. Conyngham, Dalziel B. McGrigor, Richard G. S. Gregg, William A. Spong, Herbert W. Carson, Henry P. Hart, Francis T. Dowling, Richard F. O'T. Dickinson, Harold T. Treves, James C. L. Hingston, Arthur E. B. Jones, Benjamin A. Odlum, Alexander Hendry, Charles P. O'Brien Butler, John R. Lloyd, and James F. Grant.

Major John H. Rivers retires on retired pay (dated Feb. 25th, 1911).

Lieutenant-Colonel J. Will, at present in medical charge of the troops at Kinsale, has been selected for the appointment of Staff Officer to the Administrative Medical Officer, Northumbrian Division, at Richmond, Yorks, with effect from April 1st next. Lieutenant-Colonel M. O'D. Braddell, commanding the Station Hospital at Lahore, has been granted six months' leave of absence on medical certificate. Lieutenant-Colonel W. W. Pike, D.S.O., in charge of the Military Hospital at Tidworth Park, has been placed under orders for service in Egypt. Lieutenant-Colonel C. W. Johnson, from Gibraltar, has taken over charge of the Military Hospital at Bulford Camp, Salisbury Plain. Major D. J. Collins has been appointed to officiate as Staff Officer to the Principal Medical Officer of the Irish Command. Major G. A. Moore, on the completion of the tenure of his appointment, has been transferred from the medical charge of the Royal Military Academy, Woolwich, for duty at Chatham as Specialist in Laryngology. Major F. W. Begbie, from Colchester, has been placed under orders to join at Tidworth Park as Assistant Administrative Medical Officer for Royal Army Medical Corps Training. Major H. D. Packer has been transferred from Devonport to Exeter. Major G. H. Goddard, from Alderney, has taken up duty at Shorncliffe. Captain G. S. C. Hayes, from the London District, has been appointed Medical Officer to the 1st Life Guards at Windsor. Captain E. B. Booth has been appointed for duty in the Irish Command. Captain J. G. Gill has been granted six months' general leave of absence home from India. Captain J. T. Johnson has been transferred from Sheffield to Newcastle. Captain R. J. Cahill, on completion of a tour of service in India, has been posted to the Curragh Camp for duty. Captain A. C. Vidal, from Pretoria, has taken up duty at Bloemfontein. Captain C. D. Myles, from Cosham, has joined at Gosport. Captain A. C. Amy has been appointed Specialist in Radiography and Electrical Science to the Seventh (Meerut) Division. Lieutenant H. G. Robinson has been transferred from Sheffield to Litchfield. Lieutenant G. Rollaston has been appointed to the West African Medical Staff, Sierra Leone Protectorate, from the Special Reserve. Lieutenant S. W. Kyle, from Mullingar, has taken up duty at Belfast. Lieutenant P. E. C. Pottinger has embarked for a tour of service in India.

### INDIAN MEDICAL SERVICE.

Colonel C. H. Beatson has arrived home on leave. Colonel G. W. P. Dennys has taken over the duties of Principal Medical Officer of the Derajat and Bannu Brigades. Lieutenant-Colonel A. J. Macnabb has been appointed Presidency Surgeon of Kashmir by the Foreign Department of the Government of India. The Honourable Lieutenant-Colonel C. Mactaggart, Inspector-General of Prisons in the United Provinces, has been granted leave of absence from India for one year and eight months. Lieutenant-Colonel A. W. Dawson has been appointed to hold Civil Medical Charge of Roorkee Cantonment. Lieutenant-Colonel J. Crimmin, V.C., C.I.E., has been appointed by H.E. the Governor of Bombay to act as Presidency Surgeon, in succession to Major S. H. Burnett, proceeding on leave. Lieutenant-Colonel R. J. Marks has been posted as Civil Surgeon to Gorakhpur. Lieutenant-Colonel W. A. Sykes has arrived home on leave of absence from India. Major A. W. T. Buist has been appointed Civil Surgeon at Ambala. Major W. Selby has been transferred from Gorakhpur to Lucknow as Civil Surgeon. Major T. B. Kelly has been appointed a Specialist in Ophthalmology. Major J. M. Crawford, on return from leave, has taken over duty as Civil Surgeon of Benares. Major A. Miller, Madras Presidency, has arrived home on leave. Captain W. J. Powell, on return from furlough, has been appointed to officiate as Superintendent of the Central Jail at Jubbulpore. Captain C. W. Cazaly has been appointed Specialist in Advanced Operative Surgery to the Fifth (Mhow) Division. Captain D. N. Anderson has been granted six months' extension of his leave, on medical certificate. Captain G. Fowler, civil surgeon of Akola, has been deputed to attend the investigations in connexion with malarial fevers at Amritsar. Captain C. A. F. Hingston, personal assistant to the surgeon-general with the government of Madras, has been appointed Medical Inspector of Factories in the Madras Presidency. Captain C. Dykes has been transferred from Saharanpur to Jaunpur as Civil Surgeon. Captain E. T. Harris has been granted eight months' leave of absence from India. Captain F. F. Elwes, Surgeon to H.E. the Governor of Madras, has been appointed District Medical and Sanitary Officer at Cuddapah. The services of

Captain C. R. O'Brien have been placed permanently at the disposal of the Government of Eastern Bengal and Assam. Captain D. Munro, Bengal Presidency, has arrived home on leave. Lieutenant W. T. Keyworth has been appointed Specialist in Midwifery and Diseases of Women and Children to the Sixth (Poona) Division. Lieutenant A. A. C. McNeill has been appointed to officiate in medical charge of the 51st Sikhs and No. 3 Company Sappers and Miners at Peshawar.

SPECIAL RESERVE OF OFFICERS.

*Royal Army Medical Corps.*

The undermentioned lieutenants are confirmed in their rank:—James B. Williamson, Claude Johnson, John Adams, David T. M. Large, David T. Richardson, William L. Webster, and Frederick W. Lumsden.

TERRITORIAL FORCE.

*Royal Field Artillery.*

1st South Midland (Gloucestershire) Brigade, Royal Field Artillery: Surgeon-Captain James R. Bibby resigns his commission (dated Feb. 25th, 1911).

*Royal Army Medical Corps.*

2nd Home Counties Field Ambulance, Royal Army Medical Corps: Lieutenant Edwin A. Houchin is restored to the establishment (dated Dec. 15th, 1910).

5th London Field Ambulance, Royal Army Medical Corps: Lieutenant Robert Corfe to be Captain (dated Dec. 1st, 1910).

3rd Northumbrian Field Ambulance, Royal Army Medical Corps: August Frederick Perl to be Lieutenant (dated Jan. 14th, 1911).

3rd London (City of London) Field Ambulance, Royal Army Medical Corps: Lieutenant Harold A. T. Fairbank to be Captain (dated August 30th, 1910).

1st Scottish General Hospital, Royal Army Medical Corps: The undermentioned officers retire under the provisions of Paragraph 75 of the Territorial Force Regulations (dated Feb. 25th, 1911):—Lieutenant-Colonel John Gordon and Major George Rose.

*For attachment to Units other than Medical Units.*—Major John Alfred Masters, from the 2nd London (City of London) Field Ambulance, Royal Army Medical Corps, to be Major (dated Jan. 23rd, 1911).

*Attached to Units other than Medical Units.*—Lieutenant Alan L. S. Tuke to be Captain (dated Dec. 10th, 1910). Lieutenant-Colonel Charles C. Greig retires under the provisions of Paragraph 116 of the Territorial Force Regulations, and is granted permission to retain his rank and to wear the prescribed uniform (dated Feb. 25th, 1911). Lieutenant Edward Oliphant resigns his commission (dated Feb. 25th, 1911). Major James A. Rigby resigns his commission, and is granted permission to retain his rank and to wear the prescribed uniform (dated Feb. 22nd, 1911).

*Unattached List for the Territorial Force.*—Stuart McDonald to be Second Lieutenant for service with the Durham University Contingent, Senior Division, Officers Training Corps (dated Feb. 1st, 1911).

STAFF TOUR FOR R.A.M.C. OFFICERS.

The following officers assembled at Colchester and took part in a medical staff tour which was held from Feb. 27th to March 2nd inclusive:—Surgeon-General J. C. Dorman, C.M.G.; Brigadier-General J. H. L. Haldane, C.B., D.S.O. (General Staff); Lieutenant-Colonel M. W. Russell, Lieutenant-Colonel W. G. Birrell, Lieutenant-Colonel D. V. O'Connell, Lieutenant-Colonel C. A. Lane, Major H. E. Winter, Major G. A. T. Bray, Major G. S. Mansfield, Major S. H. Fairrie, and Major A. W. Cooper, D.S.O.

THE VISION OF RECRUITS.

In view of the difficulty experienced by men who fire from the left shoulder in maintaining the necessary rapidity of rifle fire, the Army Council has decided as an experiment for one year to exclude from the Infantry, Cavalry, Artillery (except drivers), and Royal Engineers (except drivers) recruits whose vision is below 6/24 in the right eye, but who, if they reach the standard of 6/6 in the left eye, are accepted under existing regulations. When a recruit is below the 6/24 standard in the left eye he will not be accepted unless he possesses normal vision in the right eye. As this experiment is only applicable to the arms mentioned above, recruits rejected under it continue to be eligible for other corps and services.

# Correspondence.

"Audi alteram partem."

## CHARLES BELL AND THE MOTOR AND SENSORY FUNCTIONS OF SPINAL NERVES.

*To the Editor of* THE LANCET.

SIR,—The heading of this correspondence should be: "Did Bell or Magendie discover the motor and sensory functions of the anterior and posterior roots of the spinal nerves?"

Professor Keith is in error in his statement somewhat floridly made in your last issue to the effect that I quoted my own text-book as authoritative concerning the historical facts in connexion with the discovery of the motor and sensory functions of the spinal nerve roots made according to Professor Keith by Charles Bell and according to me by Magendie. I only quoted what I had written 20 years ago, accompanied by references to the original papers at my elbow, by which the accuracy of my statements could be verified or the reverse. Professor Keith believes that the discovery belongs to Sir Charles Bell, and without having himself given any actual quotation in support of his belief, says that it would be well for me to quote from the original work of the author in dispute so that readers of THE LANCET may form an unbiassed opinion. I will do so.

The original documents—neglecting "reproductions" and polemical misquotations subsequent to the year 1822—are in last resort, or in first resort: 1. Charles Bell: "Idea of a New Anatomy of the Brain," submitted for the observations of his friends by Charles Bell, F.R.S.E. (small 8vo, pp. 36, published by Strahan and Preston, printers, London; without date, but on collateral evidence the date 1811 is accepted, in spite of the date 1802, which is that assigned to it in the 1885 catalogue of the British Museum). A copy also exists in the library of the Royal Society, presented to it 18 years ago by Professor Jeffrey Bell. II. Magendie: "Expériences sur les Fonctions des Nerfs Rachidiens." (Experiments on the Functions of the Spinal Nerves). Journal de Physiologie Expérimentale et Pathologique, par F. Magendie. Tome II., année 1822, pages 276–9.

Two papers by Charles Bell in the Philosophical Transactions of the Royal Society for 1821 and 1822,[1] dealing with the nerves of respiration and with the nerves of the face, are only indirectly connected with the subject. The subsequent controversies alluded to by Professor Keith, and, in fact, all publications posterior to the date 1822, are without value as direct evidence bearing upon the main question. I therefore shall confine myself to that question as recorded in the two essential documents. Both are accessible, and the accuracy and completeness of my quotation and translation can therefore be readily verified.

I.—Bell, 1811: "Idea of a New Anatomy of the Brain (p. 21)—

I took this view of the subject. The *medulla spinalis* has a central division, and also a distinction into anterior and posterior fasciculi, corresponding with the anterior and posterior portions of the brain. Further, we can trace down the crura of the *cerebrum* into the anterior fasciculus of the spinal marrow, and the crura of the *cerebellum* into the posterior fasciculus. I thought that here I might have an opportunity of touching the *cerebellum*, as it were, through the posterior portion of the spinal marrow and the *cerebrum* by the anterior portion. To this end I made experiments which, though they were not conclusive, encouraged me in the view I had taken. I found that injury done to the anterior portion of the spinal marrow convulsed the animal more certainly than injury done to the posterior portion; but I found it difficult to make the experiment without injuring both portions.

Next, considering that the spinal nerves have a double root and being of opinion that the properties of the nerves are derived from their connections with the parts of the brain, I thought that I had an opportunity of putting my opinion to the test of experiment, and of proving at the same time that nerves of different endowments were in the same cord, and held together by the same sheath.

On laying bare the roots of the spinal nerves, I found that I could cut across the posterior portion of the spinal marrow without convulsing the muscles of the back; but on touching the anterior fasciculus with

[1] On the Nerves: Giving an Account of Some Experiments on their Structure and Functions, which lead to a New Arrangement of the System. Phil. Trans. R.S., 1821, pp. 398–424. The subject-matter of this inquiry is limited to the nerves of respiration. The subject is prosecuted in the next paper: Of the Nerves which Associate the Muscles of the Chest in the Actions of Breathing, Speaking, and Expression. Being a continuation of the paper on the Structure and Functions of the Nerves. Phil. Trans. R.S., 1822, pp. 284–312.

the point of the knife, the muscles of the back were immediately convulsed.

Such were my reasons for concluding that the *cerebrum* and the *cerebellum* were parts distinct in function, and that every nerve possessing a double function obtained that by having a double root. I now saw the meaning of the double connection of the nerves with the spinal marrow; and also the cause of that seeming intricacy in the connections of nerves throughout their course, which were not double at their origins.

The spinal nerves being double, and having their roots in the spinal marrow, of which a portion comes from the *cerebrum* they convey the attributes of both grand divisions of the brain to every part; and therefore the distribution of such nerves is simple, one nerve supplying its destined part. But the nerves which come directly from the brain come from parts of the brain which vary in operation; and in order to bestow different qualities on the parts to which the nerves are distributed, two or more nerves must be united in their course or at their final destination. Hence it is that the 1st nerve must have branches of the 5th united with it: hence the *portio dura* of the 7th pervades everywhere the bones of the cranium to unite with the extended branches of the 5th: hence the union of the 3rd and 5th in the orbit: hence the 9th and 5th are both sent to the tongue: hence it is, in short, that no part is sufficiently supplied by one single nerve, unless that nerve be a nerve of the spinal marrow, and have a double root, a connection (however remotely) with both the *cerebrum* and *cerebellum*.

p. 26—

The *cerebellum* when compared with the *cerebrum* is simple in its form. It has no internal tubercles or masses of cineritious cortex, and forms the *crus*; and the *crus* runs into union with the same process from the *cerebrum*; and they together form the *medulla spinalis*, and are continued down into the spinal marrow; and these crura or processes afford double origin to the double nerves of the spine. The nerves proceeding from the *Crus Cerebelli* go everywhere (in seeming union with those from the *Crus Cerebri*); they unite the body together, and control the actions of the bodily frame; and especially govern the operation of the viscera necessary to the continuance of life.

p. 27—

The cerebrum I consider as the grand organ by which the mind is united to the body. Into it all the nerves from the external organs of the senses enter; and from it all the nerves which are the agents of the will pass out.

p. 36—

The secret operations of the bodily frame, and the connections which unite the parts of the body into a system, are through the cerebellum and nerves proceeding from it.

No unprejudiced reader possessing even a slight acquaintance with the state of anatomical and physiological knowledge at the beginning of last century can fail to recognise that Bell in saying "that every nerve possessing a double function obtained that by having a double root" used the word "double" to denote *cerebral* and *cerebellar*, not motor and sensory. In Bell's view the spinal nerves being double, with roots from the cerebrum and from the cerebellum, convey the attributes of both grand divisions of the brain to every part (p. 23).

Cerebral (anterior) in Bell's idea is motor and sensory. Cerebellar (posterior) is visceral ("governing the operations of the viscera"—p. 26—"controlling the secret operations of the bodily frame"—p. 36).

That is the real meaning of Bell's argument, and it is entirely consistent with the one experimental fact brought forward in the pamphlet. Every physiologist who has repeated the experiment knows that in a recently killed animal the "posterior fasciculus of nerves" is inexcitable and the anterior fasciculus excitable (p. 22). But to infer from this fact alone that the posterior are sensory and the anterior motor was at that time, and would be now, wholly unwarrantable. And as a matter of historical fact Bell did not do so.

II.—Magendie, 1822. Experiments on the Function of the Roots of the Spinal Nerves. (*Journal de Physiologie*, tome ii., 1822, pp. 276–9.)

I had long desired to make an experiment in which I should cut on an animal the posterior roots of the nerves that spring from the spinal cord. I had attempted to do so many times without success on account of the difficulty of opening the vertebral canal without injuring the cord, thereby causing the death, or at least serious injury, of the animal. Last month a litter of eight little dogs, aged 6 weeks, were brought to my laboratory; these animals appeared very suitable for my purpose, and in fact I was able with a sharp scalpel almost by a single stroke to expose the posterior half of the spinal cord surrounded by its sheaths. In order to expose the cord almost completely it was only necessary to cut through the dura mater; this was easily done, and I then had under my eyes the posterior roots of the lumbar and sacral nerves which being raised successively by the blades of a small pair of scissors could be cut on one side, the cord remaining intact. I did not know what would be the result of this proceeding. I closed the wound by a suture through the skin and observed the animal. At the outset I thought that the limb corresponding to the divided nerve was entirely paralysed; it was insensitive to pricking and to the strongest compression; it also appeared to be immobile, but before long to my great surprise I saw it move in a very evident manner although its sensibility remained absolutely abolished. A second and a third experiment gave me exactly the same results. I began to regard as probable that the posterior roots of the spinal nerve might have functions different from those of the anterior roots and that they were especially concerned with sensibility. It naturally occurred to one to cut the anterior roots, leaving the posterior roots intact, but this undertaking was more easy to conceive than to execute. How was it possible to expose the anterior part of the cord without interfering with the posterior roots? I confess that at first this seemed impossible, but the idea pursued me for two days and at last I made up my mind to attempt to get a sort of cataract knife in front of the posterior roots with a very narrow blade enabling me to cut the roots by compressing them between the edge of the knife and the posterior surface of the vertebræ, but I was obliged to abandon this attempt on account of the large veins in the vertebral canal. In making these attempts I noticed that by traction of the vertebral dura mater it was possible to distinguish the anterior roots grouped in bundles at the point where they emerge from the membrane. That was enough for me and in a few moments I had divided all the pairs that I wanted to divide. As in previous experiments I divided the nerve on one side only in order to have a term of comparison. It may be imagined with what curiosity I watched for the effects of this operation. There was no room for doubt, the limb was completely immobile and flaccid while it preserved an unequivocal sensibility. Finally for the sake of completeness I have cut at the same time the anterior and the posterior roots; sensation and motion were then absolutely lost.

I have repeated and varied these experiments on many kinds of animals; the results that I have just described have been completely confirmed for the anterior as well as for the posterior roots. I am continuing these experiments and shall give a more detailed account of them in the next issue. I content myself with laying down at present as positive that the anterior and posterior roots of the nerves that spring from the spinal cord have different functions, that the posterior appear to be more specially appropriated to sensation while the anterior appear to be more especially associated with movement.

Comparing these two descriptions, I think it must be obvious that the case as presented by Magendie in 1822 is clarity itself as compared with that given by Bell in 1811. No other part of Bell's pamphlet (nor any portion of his Philosophical Transactions papers of 1821 and 1822) helps to make his case any clearer—on the contrary. No unprejudiced reader can fail to understand that Bell did *not* discover the motor and sensory functions of the spinal roots, and that Magendie actually did so. To speak of a "Bell-Magendie" law is a weak compromise

The sentence quoted from my text-book of 1891 in my first letter to the effect that "The facts were discovered by Magendie (1822)," and that "Charles Bell (1811) to whom the discovery is commonly ascribed, observed motion on excitation of the anterior roots of a recently killed animal, and inferred that the anterior or 'cerebral' roots are motor and sensory, and that the posterior or 'cerebellar' roots serve to govern vital actions" (*loc. cit.*, 3rd ed., p. 485) is as accurate as is possible in a small number of words. No statement subsequent to 1822 is "*authoritative.*"

I am, Sir, yours faithfully,

A. D. WALLER,
Physiological Laboratory, University of London, S.W.

## THE TREATMENT OF MALIGNANT STRICTURE OF THE ŒSOPHAGUS, WITH ESPECIAL REFERENCE TO INTUBATION AND TO RADIUM.

*To the Editor of* THE LANCET.

SIR,—In your last issue (Feb. 25th) there appears a very generous and excellent summary of my communication to the Medical Society of London on Feb. 13th on this subject, but there occurs one printer's error which, if left uncorrected, would lead to an entirely wrong impression of my radium treatment, the essential feature of which is the employment of large quantities. Near the end of the article Dr. Finzi and I are credited with "using from 50 to 20 milligrammes on the gullet for periods varying from 12 to 28 hours on end, repeated in some instances as many as six times." A cypher has obviously been omitted by the printer, for the amounts mentioned by me were "50 to *200* milligrammes" of pure radium salt. Twenty milligrammes is a very small dose to employ in a malignant tumour of any size, and though Dr. Morton claims to have obtained some substantial results with about 34 milligrammes of radium salt (which by a slip he describes as "pure radium"), yet I should strongly object to any endeavour to check the claims made by Dr. Finzi and myself being based on the employment of anything less than 50 milligrammes, which was the minimum amount used in our earlier cases. With the larger doses of 100 and 150 and 200 milligrammes our later results have commensurately improved. I have heard of several hospital and private patients with malignant disease in the gullet or in the throat who have been submitted to, what is really, though not intentionally, a bogus radium treatment. At one very large hospital *two* milligrammes of radium were applied for 18 or

22 hours respectively in the gullet of two patients suffering from cancer, and at two other large hospitals insignificant doses of radium salt have been applied for an inadequate time. These applications were made in good faith by those who probably did not then appreciate the uselessness of such very small amounts, but the employment of inadequate doses in hospital and private practice by practitioners without technical knowledge or experience either of radium or of gullet work will, if persisted in after this protest, come very near to quackery.

There is another point of technique mentioned in your report of the subsequent discussion which, if followed, will, in my opinion, be not unlikely to lead to occasional disaster. Mr. Tilley is represented as saying that "when an anæsthetic was required for endoscopy of the œsophagus chloroform was better than ether." Mr. Tilley, as a matter of fact, put the question of choice of anæsthetic more strongly than that; he said that ether was contra-indicated and that chloroform was *the* anæsthetic to employ in œsophagoscopic procedures. To this sweeping pronouncement I strongly dissented. In some cases where the heart is sound and the patient not debilitated chloroform may be safely and preferably administered in gullet work, and it undoubtedly causes less local congestion than ether anæsthesia alone, more especially if the latter is given by the closed method before the endoscope is introduced; moreover, ether by the closed method is contra-indicated where, as frequently happens, there is much laryngeal involvement or irritation, and in cases with abductor paralysis; but chloroform alone also has its disadvantages, and is contra-indicated in those cases to which Mr. Tilley alluded in another connexion—viz., those with a tendency to syncope when the endoscope is introduced; in other words, in patients debilitated by semi-starvation and toxæmia from advanced disease and whose hearts are weak. To give chloroform *alone* in such cases is to court disaster. It is for this reason that Chevalier Jackson, an œsophagoscopist of enormous experience, insists on ether as the main anæsthetic with occasional whiffs of chloroform. Dr. G. A. H. Barton, who anæsthetises my private patients, relies mainly on the chloroform and ether mixture given by the *open* method in cases with a weak heart; this can be alternated with spells of chloroform alone after the heart has been sufficiently stimulated by the C.E. mixture.

Another point of anæsthetic technique seriously recommended has only to be stated to carry its own refutation with it. Mr. Tilley came to the meeting provided with an œsophagoscopic tube, together with Mr. Bellamy Gardiner's anæsthetic tube, which can be linked up with the proximal end of the œsophagoscopic tube. This well-known apparatus Mr. Tilley displayed to the audience and handed to the President, and explained that the chloroform was pumped through the Bellamy Gardiner anæsthetic tube into the œsophagoscope! We may be quite sure that neither Mr. Bellamy Gardiner nor any other anæsthetist in his senses would dream of administering a general anæsthetic *through the œsophagoscope*, not even in those cases where there is a communication between the gullet and the air passages.

There are other points of œsophagoscopic technique on which I do not see eye to eye with Mr. Tilley, but they are too technical for discussion outside the Laryngological Section. It was very evident to those present who were really expert in endoscopic procedures in the gullet that, absent-mindedly wandering from the subject under discussion, Mr. Tilley was *talking* œsophagoscopy and *thinking* bronchoscopy, of which latter he is admittedly such an experienced and accomplished exponent.

I am, Sir, yours faithfully,

Weymouth-street, W., Feb. 27th, 1911. WILLIAM HILL.

## THE LANTERN TEST FOR COLOUR BLINDNESS.

*To the Editor of* THE LANCET.

SIR,—In reference to the letter of Mr. Buxton in THE LANCET of to-day, in which he says that in many particulars his lantern anticipated mine, I should like to point out that I am not aware of any lantern which has anticipated any essential point of mine. My lantern was constructed more than 22 years ago, and has never been altered in any important particular. A full description of the lantern was published in my pamphlet "On the Detection of Colour Blindness from a Practical Point of View"[1] in 1889, at which time I was a member of the International Code of Signals Committee.[2] I took up the subject of colour blindness for my thesis for M.D. After the publication of my papers numerous lanterns were brought out. I tested some of these with persons that I knew to be colour blind, and with some failed to detect a single colour-blind person. I will now deal with Mr. Buxton's statement in which he says that in two points his lantern possesses an advantage over mine. He says that with his the illumination can be readily varied; this is accomplished in my lantern by means of the neutral glasses. The second supposed advantage is that of comparing the wools with the light; this method was originally employed by me (see my book on "Colour Blindness," first edition, page 115). The objection to this method is that it cannot be employed in the dark, and is therefore more suitable for the classification test, but anyone can if he wish use this method with any lantern. My tests were all based on the special facts of colour blindness which I was the first to discover. Most of these facts have now been rediscovered (probably independently) by other persons and claimed as new by them. A few days ago an ophthalmic surgeon wrote to me about a lamp which he had purchased which was said to be mine and was made by a maker of whom I had not previously heard. I also find that these lamps, which may be useless, are being extensively advertised on the continent.[3] The essential parts of my lantern are the glasses. I differ from Mr. Buxton in his opinion that the colours of his glasses are almost identical with mine. I discovered that there were cases of shortening of the red end of the spectrum without any other defect of colour perception. These cases fail to see a red of a certain wave-length, therefore it is absolutely necessary that the lantern should be able to show a red consisting only of these rays. It is not possible to show a red of this kind with Mr. Buxton's lamp. I have examined all his glasses with my spectrometer and I would not pass or use any one of them in my lantern. They are very defective from my point of view. I can obtain numerous important combinations with my lantern; no combinations at all are possible with Mr. Buxton's instrument. The neutral glasses of my lantern are also absolutely necessary. In reference to the concluding remarks, I may mention that the Admiralty are now using my lantern and that Fleet-Surgeon Pryn reported on it as the best form of lantern.

I am, Sir, yours faithfully,

F. W. EDRIDGE-GREEN.

The Institute of Physiology, University College, Gower-street, London, Feb. 25th, 1911.

## THE PHILADELPHIA IDEA AS TO MEDICAL TEACHING.

*To the Editor of* THE LANCET.

SIR,—On several occasions within the last few years statements have been made in medical journals, here and abroad, to the effect that the medical schools of this country are not equipped with satisfactory opportunities for clinical teaching. Last spring the President of Cornell University, when delivering an address which should have been carefully prepared, made the extraordinary statement that no medical school in this country, with the exception of Johns Hopkins, had a hospital completely under its control, and therefore adequately used for teaching purposes. In the issue of THE LANCET of Feb. 4th, 1911, your correspondent in describing a proposed amalgamation between the medical department of Columbia University and the Presbyterian Hospital, refers to this plan as the "Johns Hopkins idea." It goes without saying that those of us who know much of medical teaching hold the Johns Hopkins medical department in the highest esteem, but it is only proper that the correct facts be stated. The object of this communication is to point out the fact (not as generally known as it should be) that every medical school in Philadelphia has as a part of its equipment a hospital which exists, not as an affiliated

[1] London: Baillière, Tindall, and Cox.

[2] See THE LANCET, Oct. 19th (p. 797) and Nov. 30th (p. 1146), 1889. See also a leading article in THE LANCET of Nov. 9th, 1889, p. 964.

[3] My lantern can be obtained from Messrs. Reiner and Keeler, 9, Vere-street, W.

institution, but as part and parcel of its teaching plant. As long ago as 1824, when the Jefferson Medical College was founded, it established an out-patient service in order to give its students the advantage of clinical material under its own control, and in 1841 the medical department of the University of Pennsylvania did likewise. In 1873 the Jefferson College inaugurated its plan for a complete hospital, and this institution was opened Sept. 17th, 1877, containing 160 beds. On June 4th, 1874, the hospital of the University of Pennsylvania went into active service. Three years ago the new Jefferson Medical College Hospital, costing $1,250,000, was completed, containing 300 beds, and from time to time the University Hospital has been considerably enlarged. As soon as it was started in 1881 the Medico-Chirurgical College established an out-patient department, and a few years afterwards erected a hospital. The Woman's Medical College of Pennsylvania also has a hospital known as the Hospital of the Woman's Medical College. The Hahnemann Medical College, the largest homœopathic school in this country, also has its own hospital, and the medical department of Temple University, the youngest of the Philadelphia schools, has under its direct control the Samaritan Hospital. It is interesting to note in this connexion that all of these hospitals are under the control of the same boards of trustees as govern the institutions in which the students matriculate for the purpose of studying medicine, and in the Jefferson Medical College, in the University, and in the Medico-Chirurgical College, members of the Faculty who teach in the practical branches are by virtue of their professorial chairs in actual control and on duty in the wards. In other words, to be elected professor of medicine, therapeutics, or surgery in the Jefferson College means that a man is elected physician or surgeon to the Jefferson Medical College Hospital. It is therefore a matter of absolute control and not of friendly affiliation, and by this means only can satisfactory medical teaching in the medical school be accomplished. If, therefore, the principle of having an active hospital as a part of a thoroughly equipped medical school is to be given a specific name it should be called the "Jefferson College Idea" or the "Philadelphia Idea" and not the "Johns Hopkins Idea." As a matter of fact, barring the Johns Hopkins Hospital, there is, I believe, no other medical school in the United States so thoroughly equipped with hospital facilities under its own control as each of the Philadelphia medical teaching institutions. All of these institutions have, in addition, the opportunity of teaching their students in large hospitals which are thrown open to all the schools, such as the Pennsylvania and Philadelphia hospitals, for example. In other words, the Philadelphia schools have all the benefit of unattached hospitals possessed by institutions elsewhere, and in addition their ownership and control of their own hospitals.

As a matter of historical fact, the Jefferson College was the first medical institution in America to establish clinical teaching, and all its sister institutions in Philadelphia, with which it dwells in the most cordial friendship, have followed her example.

I am, Sir, yours faithfully,

Philadelphia, U.S.A., Feb. 11th, 1911. H. A. HARE.

## DISEASES OF ELEPHANTS' TUSKS.

*To the Editor of* THE LANCET.

SIR,—I have been interested in reading Mr. Bland-Sutton's paper on the above subject read before the Hunterian Society, published in THE LANCET of Nov. 26th, 1910. It recalls to my mind the case of a tusk of an elephant which was found in this country tightly wedged between branches of a tree. Examination of the tusk showed that there had evidently been disease at its root, no doubt inflammation of the pulp, with probable abscess formation, and the evidence all goes to show that the suffering giant had managed to attain to the extraction of the offending member. It was impossible to assign a cause, but probably a bullet, as in the case quoted by Mr. Bland-Sutton, was at the root of the evil.

I have also in my possession the tushes of a hippopotamus I shot in Lake Nyasa, of which one of the lower curved teeth shows a cavity on its grinding surface opening into the pulp chamber with resulting periodontal inflammation and the laying down of a quantity of new dentine round the root. Of aberrant teeth I have an example in the skull of an old-man baboon, one of whose upper canines had been thrust out of line by the other teeth; this had grown long and projected out of the mouth, and must have served as a formidable weapon of offence in making the side-way slashes as they do when attacking.

I am, Sir, yours faithfully,

HUGH S. STANNUS, M.B. Lond.,
Medical Officer, Nyasaland Administration.

Zomba, Nyasaland, Jan. 16th, 1911.

## THE LATE DR. JAMES EDMUNDS AND CÆSAREAN SECTION.

*To the Editor of* THE LANCET.

SIR,—In your obituary notice of Dr. James Edmunds, I am surprised to see no mention of his two cases of Cæsarean section performed in 1860 and 1876 with success to both mothers and children (one child subsequently died). These two cases aroused a good deal of attention from the circumstance that Dr. Edmunds deliberately refrained from suturing the uterine wound. I suppose he was the only British operator who could say that he had successfully performed Cæsarean section over 50 years ago. His cases are interesting items in the history of Cæsarean section, and I should like again to call attention to them in the pages of the journal in which they were published so long ago as apparently to have escaped the observation of the writer of the obituary notice.[1]

I am, Sir, yours faithfully,

Harley-street, W., Feb. 27th, 1911. HERBERT R. SPENCER.

## ADMISSION OF CASES OF MEASLES AND WHOOPING-COUGH TO THE HOSPITALS OF THE METROPOLITAN ASYLUMS BOARD.

*To the Editor of* THE LANCET.

SIR,—Misunderstanding seems to have arisen in some quarters as to the scope of the Order recently issued by the Local Government Board empowering the Metropolitan Asylums Board to receive into their hospitals cases of measles and whooping-cough. I should therefore be glad if you would kindly allow me to inform medical practitioners and others through your columns that this Board are only authorised to admit poor persons, under 16 years of age, on the order of a relieving officer, or master of a workhouse, or medical superintendent of an infirmary or district sick asylum, or the superintendent of a Poor-law school, accompanied by the certificate of a Poor-law medical officer.

I am, Sir, your obedient servant,

T. DUNCOMBE MANN,
Clerk to the Board.

March 1st, 1911.

## THE TREATMENT OF A CASE OF PERNICIOUS ANÆMIA.

*To the Editor of* THE LANCET.

SIR,—I think the following note may interest some of your readers.

The patient was a man, aged 68 years, belonging to the labouring classes. He was treated with increasing doses of arsenic (by the mouth) for ten days without any sign of improvement. In his own cottage it was difficult to obtain for him the proper amount of fresh air or light. I was fortunate enough to find, close to my own house, a good room where there was plenty of the two latter requisites, and where there was also a housewife who ably seconded me in all my efforts. At this time his blood count, as estimated by the Clinical Research Association, was as follows: Red corpuscles, 3,700,000 per c.mm., or 74 per cent.; white corpuscles, 3000 per c.mm. I now treated him with iron and arsenic hypodermically in the following doses, twice a day, by means of the very convenient B.W. vaporoles—viz., ferr. citrat. virid. 0·05 gm., sodii arsenat. 0·002 gm., aquam ad 1 c.c. In a few days I administered this dose three times a day, and it was well borne. The improvement

[1] See THE LANCET, 1861 vol. i., p. 4; and 1876, vol. ii., p. 818.

in many ways was very great. Formerly, at home, he had practically eaten nothing and cared only to stay in bed. He now ate and drank all that was given him, and was always ready to rise from bed in the afternoon. After six days his blood count was as follows: Red corpuscles, 5,100,000 per c.mm., or 102 per cent.; white corpuscles, 3000 per c.mm. The general improvement was, however, not maintained. He had to return home, and gradually the disease obtained the upper hand.

Pernicious anæmia, of course, shows remarkable remissions, but the rapid improvement in the blood count after the hypodermic treatment seems to hold out some hope for the cases of younger and more vigorous patients, especially if it were begun soon enough. I did not see my patient until the case was at least four months advanced according to history, and quite possibly more.—I am, Sir, yours faithfully,

East Meon, Hants, February, 1911. EDWARD T. JONES.

# EXPERIMENTS IN SEWER VENTILATION AT LEICESTER.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

Leicester, February, 1911.

MORE than eight years have elapsed since a detailed description was given of an ideal method of ventilating sewers.[1] At that time the system had not gone beyond the theoretical and laboratory stage. The chief fault then found was that it all seemed too good to be true. Now it is possible to speak differently, for the method has been applied during a sufficient number of years and to a large enough district to be judged from the practical results obtained. The object of the system is to prevent the ventilation of sewers in the streets or by soil-pipes on the tops of the houses. Further, greater care is displayed to prevent the intercepting traps placed between houses and sewers becoming small cesspools and to ensure more efficient ventilation of the small branch drains. A vigorous current of air may pass along the straight sewer in the street and yet have but little or no effect on the small tributary drains that come from behind the houses and down passages. The only way to ensure ventilation throughout is to place the inlets or outlets at the extreme ends of the piping. Thus there is the school of sanitary engineering that would have no intercepting trap between the house and the sewer, and by carrying every soil-pipe to the roof of the houses convert them all into sewer ventilators. The air would then have to travel the whole length of the domestic drains to get out, and there would be no neglected corners or branch drains. The ventilation of private drains and public sewers on the roofs of dwelling houses and within a few feet of bedroom windows is not, however, a very satisfactory expedient. To say that the sewer air will be blown away is not a sufficient assurance. When a neighbouring chimney catches fire the odour, and even the smoke, is blown down to the street level. Sometimes the smoke from one chimney is blown down the chimney of another house, invading, much to the surprise of the inhabitants, a room which has no fire; and where the smoke goes the air from the soil-pipes will follow.

### *Air Needed Per Head in Sewers.*

To meet these and many other objections it has been proposed to reverse the process and not allow any air to escape from the soil-pipes; but, on the contrary, to draw air down these pipes to the domestic drains and into the sewers. Here the air would be conveyed to a spot where it could be treated or safely discharged. For this artificial power is necessary, and that constitutes the first and probably the chief objection to the whole system. There is an instinctive dislike to the employment of machinery, based probably on the too frequent experience that machinery is apt to get out of order. It is therefore a good point in favour of a mechanical system if it can be shown that, in the event of a breakdown in the machinery, no very injurious consequences would ensue. Of greater importance than arguments for or against machinery is the dominating fact that in ventilating it is absolutely impossible to ensure a stable result except by the use of machinery. Just as the weather varies, so does natural ventilation vary, and this precisely in the opposite direction to our requirements, giving violent draughts in cold weather and hardly any movement of the air when it is hot and sultry. In dealing with this problem Mr. I. Shone had the advantage of experience as a mining engineer, where the entire ventilation must be artificial, though the breakdown of machinery might involve a serious loss of life. There was no hesitation, therefore, in proposing to base the ventilation of sewers on the revolutions of a fan so as to provide in all weathers exactly the volume of air required to keep the atmosphere within the sewers and drains so fresh as to be uninjurious. What this amount would be has been explained by others writing on this subject. Dr. Letheby had made experiments on the gases engendered by putrid sewage, and the results were that one cubic foot of fresh air every two minutes would suffice to dilute the air escaping from the 30 gallons, or normal daily flow of sewage per inhabitant. In other words, for every inhabitant 30 cubic feet of fresh air must be drawn every hour into the soil-pipe of the house inhabited. Obviously this cannot be done with any degree of certainty except by mechanical appliances. Having obtained this figure it was further possible to calculate that at 3*d.* per Board of Trade electric unit a "Sirocco" fan could be worked so as to provide the requisite amount of air for 1·41*d.* per annum per head of the population.

### *The Need of Cubic Measurements.*

The next point was to devise means to insure that the regulation amount of air should penetrate every soil-pipe, whether near or far from the fan. This seemed more easy to do in theory than in practice, and experience has proved the accuracy of this criticism. Originally a very elaborate inlet was provided, regulated by a vulcanite screw plug which had a small hole pierced in the centre. The size of the hole, in some places barely big enough to let a lead pencil through, varied according to the suction within the pipe, being smaller the nearer the house stood to the extraction fan. These and many other details were given by me in the first description of the system which appeared in these columns, and it is not necessary to go over the same ground again. But we have to see how far the original plan has been modified in actual application. That such experience has now been acquired is due to the enterprising spirit of the highway and sewerage committee of the Leicester Corporation. They determined to apply the system to an area of two and a half acres consisting of streets 40 feet wide with 80 six-roomed houses of the artisan class, and a population of 356 persons, or an average of 4·45 persons per house. The foul water sewers it was proposed to ventilate were 297 yards long. There is a totally separate system for storm and rain water from the surface of the streets and the roof of the houses. To convey the sewage proper there is a 12 inch pipe sewer 202 yards long and two short branches at right angles. The sewers to which the new system is applied discharge into a brick main of 3 by 2 feet, from which they are disconnected. At the junction the pipe sewer is carefully separated from the main sewer by a deep dip trap. The drains that connect the dwellings with the 297 yards of pipe sewers measure in all about 583 yards and are mostly 6 inches in diameter, while the branches to the closets and sink wastes are 4 inches. The smaller half of these have clay puddle joints instead of Portland cement for the joints. A 4 inch diameter cast iron pipe is added to the soil pipe and carried to the roof. It becomes a ventilator, but there are only 27 such ventilators to the 80 houses, in some cases six houses being connected with the one upright pipe ventilator. The cubic capacity of all these house pipes and drains is 304 cubic feet, that of the public sewer 661 cubic feet, so we have to deal with a total of 965 cubic feet, and it would take 6021 gallons to fill this with water. Now when a part of these drains and sewers were submitted to a water test it became apparent that there was a considerable leakage, amounting to seven gallons per minute. Here, then, was the first obstacle, the first great difference between the theory as demonstrated by laboratory experiments and actual application.

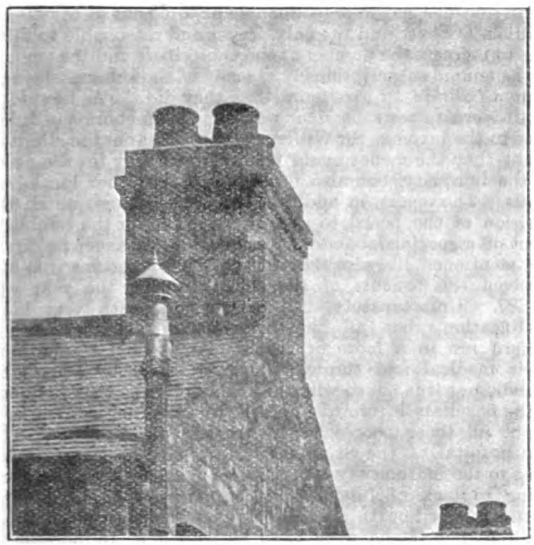
### *Leakage Upsets all the Calculations.*

At the highest point in the district a chamber was constructed under the causeway and here a "Sirocco" fan, 15 inches in diameter, driven by an electric motor capable of producing 700 revolutions per minute, was introduced. On one

[1] See THE LANCET, August 9th, 1902, p. 405.

side the chamber is connected with a flushing manhole and the air is drawn out of the sewer by the fan. On the other side the air thus extracted is forced into a ventilating shaft 40 feet high. When all was completed a five days' test was made. The velocity of the air entering the 27 soil-pipe inlets was measured by anemometers and the result showed that more air was pumped out through the extract ventilating shaft than had entered the sewers by the proper inlets. Therefore the leakage which had enabled some of the water to escape when the water test was applied now allowed some air to penetrate the sewers and drains. Thus the ideal calculations which, as said before, were all too good to be true are now upset. Given absolutely air-tight sewers and drains, with inlets all accurately measured and a fan revolving with mathematical precision, every soil-pipe would have received exactly the number of cubic feet of fresh air needed. But here was an unknown volume of air penetrating from unknown places and upsetting all these precise calculations. The mechanical part alone worked satisfactorily. The fan pumped out of the sewer exactly the right amount of air, only it did not appear that this air came from the farthest as well as the nearest inlets. At these inlets—that is to say, at the top of the 27 soil-pipes which are prolonged to the roofs of the houses—it was found, in some instances, that there was no perceptible current of air. It is true that air must travel at the rate of 30 feet per minute before it has sufficient force to move the anemometer, but the amount entering at a slower rate than this is hardly worth including in any calculation.

FIG. 1.



A cowl, constituting an air-inlet, placed on the top of the soil-pipes. The door-like opening can be seen which is used for introducing the anemometer.

Under the existing circumstances, short of re-laying all the house drains and the sewers in such a manner as to make them absolutely air-tight and keeping them in that condition for ever, a totally new set of calculations had to be made. Nor could any theoretical basis for such a reckoning be found, for no one could tell the extent of the leakages with which it was necessary to deal. Therefore, experiments had to be made with all the air inlets. Obviously much more air must be extracted so as to maintain a current through all the soil-pipes and also carry away what the leakages supplied. The minute and elaborated air inlet was too delicate an instrument for this rougher procedure. After trying many models the present system was adopted. It consists of a cylinder fitting over another cylinder. Both these have vertical apertures or slits, and the outer cylinder can be twisted round. If the apertures are made to fit over each other we have the maximum opening, but by slightly moving the outer cylinder the openings are rendered smaller and smaller till they are closed altogether. This is covered over by an ornamental hood or cowl to keep the rain off (Fig. 1). Underneath there is a commencement of piping which fits on the top of the soil-pipe, and here is the space for a small door large enough to admit a hand holding an anemometer. Thus it is necessary to place a ladder against the wall, to climb up and introduce an anemometer into this aperture. If the record shows that the amount of air descending the soil-pipe is insufficient, then the cylinder above must be turned round so as to enlarge the inlets. This descent of the air will vary from soil-pipe to soil-pipe according to its position and proximity to the extraction fan. Thus there is no rule, but a separate experiment must be made in each instance. This may seem complicated, but the needful procedure shows that the system deals with realities. According to the experiments made and the report of the borough engineer, Mr. E. George Mawbey, M.Inst.C.E., the 27 inlets measured at first only 10,278 square inches, and this might have sufficed had the sewers been absolutely air-tight. The inlets had to be increased to 75,258 square inches, and the six-inch diameter extraction shaft was replaced by a nine-inch pipe. Thus the inlet space was equal to 89 per cent. of the outlet space given by the nine-inch extraction shaft. The working showed that 752 cubic feet of air were discharged per minute by the fan into the extraction shaft; but of this only 325·53 cubic feet, or a little less than half the total volume extracted from the sewers, entered the sewers through the 27 soil-pipe inlets. In these ventilating soil-pipes of four-inch diameter the average velocity of the air was 226·2 feet per minute, representing an admission of 12·02 cubic feet per minute, or 5·23 cubic feet per house per minute, which is more than necessary. Therefore, the fan was utilised to ventilate a neighbouring sewer outside of the area devoted to the experiment. This reduced the volume of air extracted from the sewers and drains of the area to 142 cubic feet per minute, and of these 106·08 cubic feet were admitted through the 27 soil-pipe inlets, giving an average per house of 1·73 cubic feet per minute. This is a magnificent result, for in 24 hours the air within the house soil-pipes and drains is changed 502 times and replaced by air drawn from the outside atmosphere once in three minutes. Within the street sewers the air is changed about 309 times in the 24 hours, or once in four and a half minutes.

### *The Chemical Test.*

The result thus achieved, it must be borne in mind, is absolutely independent of all climatic conditions. The wind may blow or not blow from any point of the compass, the temperature may fluctuate from the extremes of heat or cold, but still pure outer air penetrates the highest point of the soil-pipe, travels down to the lowest, then on to the sewers, bearing away all noxious effluvia and preventing any accumulation or stagnation. The sewage, if foul, is constantly swept over with fresh air; there is not time for mischief to accrue. This is confirmed by chemical analyses. Outside, but close to the area, analyses were first made of the air in the street, and it contained 3·55 parts of carbonic acid gas per 10,000 parts. In the sewer the air contained in the best samples 15·95 and in the worst 24·98 parts of carbonic acid gas per 10,000 parts of air. When, however, the nine-inch extraction shaft was applied and the system in the selected area was in working order the air in the principal street of this area was found to contain 3·18 parts of $CO_2$ per 10,000, and within the sewers the average throughout the system was 9·59 parts of $CO_2$ per 10,000 parts. On another occasion the average was only 8·08, and after that it fell to 7·04 parts of $CO_2$ per 10,000 parts. Thus there can be no doubt but that the sewer atmosphere is purified by this system of ventilation. Finally, if the air from the sewer is discharged in the street, though, of course, at as high a level as possible, it will not prove as injurious as the ordinary sewer airs, which, it has been seen, contain a much larger proportion of carbonic acid gas and whatever other impurities the excessive quantity of this gas may indicate or favour.

### *The Advantages Secured.*

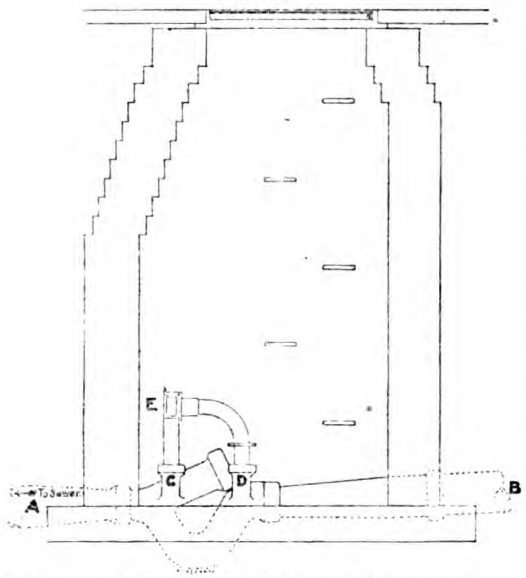
To fully appreciate these advantages it is necessary to bear in mind that at present in most cases the sewer airs travel up from the sewers to the houses, escape by numerous leakages, and are discharged either through grids into the streets or through various ventilating shafts, many placed against houses and near windows. Thus the current is always from the sewer to the street or the dwelling. But with mechanical power to produce a vacuum in the sewers the current is

reversed. Even if the sewers are badly built, if the drain-pipes are insecurely jointed, then it is pure outside air that is drawn through these leakages into the drain or sewer, and not foul air from drain or sewer that ascends and permeates the surrounding soil or dwelling. There remains, however, the old objection that all this is due to a mechanical appliance which may get out of order. If the fan is worked by an electric motor the electric current may he stopped by an accident or by a strike. In that case no more disastrous result would ensue than that of having to revert to the system of ventilation now actually applied in most towns. The inlets would once more become outlets. The worst that might have to be done would be to remove the cowl inlets that are on the top of the soil-pipes so that the latter might more readily become outlets till such time as the ventilating fan could be set in motion and the system re-established.

*The Intercepter Trap and other Obstacles.*

There is one more consideration. In many places there are intercepting traps between the house drains and the public sewer. How, then, can the air be drawn down the house drains into the sewer without forcing the water seal of these intercepting traps? For this purpose a special intercepter has been invented, and it is applied in one instance at Leicester to show how it works. (Fig. 2.) On

FIG. 2.



Paton-street, Leicester. Plan of chamber containing Messrs. Shone and Cutt's patent intercepting trap. A, Drain between intercepter and sewer. B, Drain from house to intercepter. (Of course any inlet for fresh air purposes into the house-drain B, as would be necessary under the London County Council by-laws, would require further calculations against the admission of the extra air.) C, Shaft for passage of air from house-drain to sewer. D, Shaft for passage of air from house-drain to E, box holding the suspended valve which only permits air to pass from house to sewer.

each side of the water seal there is a small opening where a pipe can be introduced and carried over to the other side of the water seal. Between the two a space is reserved where a valve is suspended in such a manner as to open and let air through from the house to the sewer, but the greater the pressure of air from the sewer towards the house the tighter this valve would be closed. It is very similar to the intercepting trap which was proposed for use in carrying out the drainage scheme for Cairo, and was described with illustrations in these columns of May 8th, 1909 (p. 1350).

For several years now this the Shone system of sewer ventilation has been working in Leicester. No accident has happened. It has given general satisfaction. The chief objection is the cost of the power that must be employed, not necessarily electricity; but all power is more or less expensive. On the other hand, the perfection of the results attained is worth a small outlay, and at the worst the cost is not great. The second objection is that the system cannot be applied like a ready-made suit of clothes. It represents, on the contrary, the highest art yet attained in this direction, and therefore requires to be tried on and fitted carefully, with intelligence and knowledge of the object to be realised. But when was a real scientific problem solved otherwise? The desire for simplicity may be exaggerated. The first sailing boats had very simple sails and rigging, but they did not sail far or quickly. The first sewers were also of very simple construction, but the greater frequency of epidemics in their days did not speak well for their sanitary qualities.

## MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

*The Manchester Hospitals.*

THE financial position of the Manchester hospitals is becoming serious enough to cause great anxiety as to the future. The Royal Infirmary, the leading medical charity, "one of the finest infirmaries in the world," as Sir William Cobbett said at the annual meeting of trustees the other day, with its very complete equipment, must live far beyond its income if it is to be used to its full capacity. To meet the expenses of the past year the board of management had "to withdraw £11,944 from unappropriated capital," and, of course, this depletion of capital cannot go on indefinitely. Sir William Cobbett said that energetic action was required to improve the position. One solution was to close 168 beds, so reducing the number to 315, or only about 25 more than the number in the old infirmary. A second was "to pay each deficiency of income as it arose, out of capital." Each of these schemes was so objectionable as to be out of court. Sir William Cobbett said the only proper and reasonable solution was to increase the number of the subscribers and the amount of the annual subscriptions, "as many of the subscribers must be in a position to give more than they did." As he said, a small increase per subscriber would make an enormous difference to the income. Sir William Cobbett had not the slightest doubt that the money could be found, not only for the needs of the infirmary but also for those of the other local hospitals. The report, in addition to other matters, stated the decision of the board to appeal for £2500 for the establishment of a special laboratory for the work of cancer research, and mentioned likewise that the number of persons who had received the benefits of the charity during the year was 67,827. Unfortunately, it may be said, with very little qualification, that all the hospitals in Manchester and Salford are in a more or less similar financial condition. Their medical and surgical work increases by leaps and bounds, but it is not so with the subscriptions. Patients flock to the hospitals in crowds, and the question naturally arises, Ought all these people to be treated gratuitously? The new hospital of the St. Mary's Hospitals, in Oxford-road, close to the infirmary, which has stood empty for some years owing to lack of funds, is to be properly equipped and opened in April next. It will be a great boon to women and children, but if the work is to be well done an increase in the subscriptions of several thousand pounds a year will be required.

*Ashton Infirmary Jubilee.*

The infirmary of Ashton-under-Lyne is to have its jubilee in the coming spring, and an effort is being made to raise £6000. Of this sum £4000 are required to clear off a debt, and the £2000 will be used for the further equipment of the infirmary. Up to the present over £2000 have been subscribed. In addition to the special appeal of the governors the workpeople's committee has decided to raise £1000 in sixpences—40,000 sixpences—and this fund is rapidly mounting up.

*Low Death-rate at Stalybridge.*

The Lancashire and Cheshire manufacturing towns do not pretend to be attractive as health resorts; but, as a rule, perhaps their reputation is lower than they deserve. However this may be, Stalybridge has been pluming itself on the last quarterly report of the medical officer of health, which shows that the births were 124 (rate 17·0) and the deaths 106 (rate 14·5). This, said the chairman of the sanitary committee, was the lowest death-rate for some time past, and "was a most marked and gratifying reduction for the winter months," and "knocked on the head" the old saying that a green Christmas meant a fat churchyard. He said

also that there had been a marked decrease during the last year or two in the deaths of young children. He thought the sanitary committee might be proud of this improvement. It is to be hoped that as the knowledge of sanitary matters permeates the lower sections of the community death-rates may still fall.

*Appointment for a Manchester Physician.*

Dr. E. S. Yonge, assistant physician to the Manchester Hospital for Consumption, has been appointed as the English representative in connexion with the Hay Fever Department of the Scientific Section of the International Hygienic Exhibition to be held at Dresden. Manchester plumes itself to some extent on its connexion with hay fever, as it is said, on what is considered good authority, that Dr. Blackley, a Manchester man, showed in 1873 that the cause of hay fever was the pollen of certain plants, especially of the graminaceæ. But the conditions determining the susceptibility of some and the immunity of others to the action of the pollen remain to be discovered. Perhaps the department at the Dresden Exhibition will throw more light on the subject.

Feb. 28th.

## LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

*Royal Liverpool Country Hospital for the Chronic Diseases of Children.*

THERE was a large and influential gathering at the dinner held at the Adelphi Hotel on Feb. 23rd in the interests of the Royal Liverpool Country Hospital, Heswall. The Earl of Derby presided, and among others present were the Countess of Sefton, Sir Thomas Barlow (President of the Royal College of Physicians of London) Sir Donald MacAlister (President of the General Medical Council), Sir Edward and Lady Russell, Sir James and Lady Barr, Sir Benjamin and Lady Johnson, Mr. B. G. A. Moynihan, Dr. W. T. Grenfell, Mr. Harold J. Stiles, Mr. Robert Jones, Dr. Charles J. Macalister, Dr. Dawson Williams, and Dr. A. Bernard (representing THE LANCET). The chairman having given the customary loyal toasts, the Lord Mayor of Liverpool proposed "Success to the Hospital" in a felicitous speech. Sir Thomas Barlow, in supporting the toast, said that there were no more severe critics of the work of physicians and surgeons than the physicians and surgeons themselves. They were conscious of the many limitations of the hospitals, which were not all due to the physicians and surgeons, but some of which arose out of the conditions under which they worked. Owing to the difficulty they had of securing that their patients should remain under their care a sufficient length of time to enable complete cures to be effected, much of their work was merely patchwork, and the results were extremely disappointing to the medical man. Often, however, the collateral results of their work were quite as important as the objects at which they directly aimed. For example, the great crusade which had been conducted against tuberculosis, besides the direct objects, brought many indirect benefits. Everybody in that room, he presumed, now made a practice of sleeping with the bedroom window open, and they were all appreciating the value of the free circulation of fresh air and sunshine. Although he had not paid it a visit until that day, the Royal Liverpool Country Hospital was an undertaking with which he had been familiar for many years. Dr. C. J. Macalister, who, with Mr. Robert Jones, was so conspicuously associated with the work, had confided to him his plans 10 or 12 years ago. One of the commendable features of the hospital was that its objects were clearly defined. Its promoters knew what they wanted to do, and were not attempting too much. They were not attempting to deal with all kinds of diseases, but had specially directed their attention to chronic cases which would require a very long time to effect complete recovery. He had been greatly impressed by the perfect happiness of the children at the hospital, and by the frugal, careful, and business-like way in which the institution was managed; and he felt he could recommend all persons engaged in the work of hospital reform to study its excellent methods. These were the days of municipalisation of everything, and it might be that eventually they would come to the municipalisation of hospitals. Well, he hoped he would never live to see that day. Liverpool, it was true, in regard to its municipal hospitals had a splendid record; all the same, he devoutly trusted that they would never permit such a hospital as they had established at Heswall to become a municipal hospital. In time he hoped that at Heswall they would make developments on educational lines by grafting into the hospital work the teaching of handicrafts and other subjects. The greatest improvements and reforms would always be found to be due to voluntary effort, and therefore he besought them to stand firmly by their voluntary institutions. Mr. Moynihan observed that the scheme of the hospital had been carried through with every circumstance of care, and the skill with which the general plan had been organised was only equalled by the enthusiasm of those interested. The toast of "The Medical Profession," proposed by Sir Edward Russell, was replied to by Sir Donald Macalister and Mr. Stiles. The former alluded to the splendid discipline which was obtained in the study of medicine. Liverpool, he said, had bred many leaders of the medical profession, and this city was now teaching many of her older sisters in medicine, especially with regard to tropical disease and hygiene. The health of the Earl of Derby was drunk on the proposition of Dr. Grenfell of Labrador. Lord Derby acknowledged the toast in a graceful and very amusing speech. The dinner was a most enjoyable one, and a number of ladies were present.

*Annual Meeting of Charities.*

At the seventy-seventh annual meeting of the trustees of the David Lewis Northern Hospital, held on Jan. 26th, the Lord Mayor presiding, much eulogy was bestowed upon the admirable work performed. Mr. Walter Holland paid a cordial tribute to the services rendered by the honorary medical and surgical staff. The number of in-patients treated during the year was 2467. 17,878 out-patients were attended to, totalling 43,297 reattendances. The second operating theatre was completed during the year.—The annual meeting of the trustees of the Royal Infirmary was held on Feb. 1st, the Earl of Sefton, the President, being in the chair. Mr. Ralph Brocklebank, the chairman of the general committee, in seconding a vote of thanks to the president, expressed the hope that the committee would be able to get the £5000 which the corporation was taking powers to obtain. He felt confident that the citizens would recognise the enormous work done voluntarily by the hospital, and generously assent to the contribution of £5000 by the corporation. Apart from legacies, which for the most part had been invested, the receipts were £16,723 and the expenditure £18,650, resulting in a deficiency of £1900, which brought the debt up to £6793.

Feb. 28th.

## BRISTOL AND THE WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

*University of Bristol: The Colston Research Fund.*

THE funds which the University Colston Society has determined to use for the encouragement of research have been allotted in grants amounting to £624 10*s.* out of a total of £900 available for the purpose. The balance has been carried forward to next year. The grants are of a catholic description, encouraging research in almost every department of the University; those of medical interest include work on the relation between the tonsils and tuberculosis of the cervical lymph glands, research into the chemistry and physiology of certain ferments within the blood in their relation to malignant disease and inflammation, and a further instalment of the work already in progress on the typhoid carrier problem. The bacteriology of diphtheria and the curdling of milk are also to be investigated. These researches will be carried on within the University and supervised by a committee representing the University and the Colston Society.

*"The Bristol Nonesuch."*

Under this attractive title the University magazine makes its first appearance in a cover of Bristol red adorned with a conventional design representing the lychnis. The true inwardness of the title is revealed by a quotation, at the head of the first page, from Gerard's Herball (published in 1633), "the floure of Bristowe or None-such ..... was called Lychnis, that is a torch or such-like light, cleere, bright and

light-giving." Not only is the name of the magazine taken from this flower, which from the above description is seen to be a most appropriate symbol of the functions of a university periodical, but also the colour, Bristol red, which is that of the University hoods. The magazine is to appear three times a year, at the middle of each term. This first number has for frontispiece a portrait of the treasurer of the University, Mr. George A. Wills, whose generous and timely gift of an athletic ground was referred to recently in these columns. A plan of the ground, with a full description, also appears in the "Nonesuch." Other notable contents are an admirably worded In Memoriam notice of the late Lord Winterstoke, "Proceedings" of the various athletic and other clubs, a paper on Student Life in the Quartier Latin, another on "Camp," and so on. Altogether it is a most promising first number, all the more so because it does not depend for its attractiveness on "special features," but merely on contributions of the type which we may expect in all future issues. The editor is to be congratulated on his vigorous seedling.

*Bristol Royal Infirmary.*

At the annual meeting of governors held on Feb. 14th a statement of finance and work during 1910 was presented. The ordinary income amounted to £13,714, exclusive of legacies, the addition of which brings the total to £19,100. This includes ordinary subscriptions to the amount of £6062, an increase of £435 over the previous year. The total ordinary expenditure amounted to £17,282, or £119 more than in 1909; to this must be added building alterations and additions amounting to £1057, and investment of certain legacies in corporation stock costing £1215, bringing the total expenditure up to £19,555. This adds £455 to the 1909 deficit, which stood at £3532, the total deficit at the end of 1910 being £3987. The total numbers of in-patients and of out-patients were 4149 and 52,813 respectively; these totals include cases remaining over from the end of 1909, and represent an increase over the work of that year. The daily average of occupied beds was 240 (out of a total of 270), the average stay of each patient was 22 days, and the average cost of each occupied bed was £55 10*s.* An appreciative reference was made to the work of the nursing staff and to the services of the honorary staff. An account of the progress of the new buildings showed that the necessary excavations had been made for the foundations, and that many thousands of tons of stone had been worked. The total cost is estimated at £70,000, of which £35,000 are in hand. A resolution was passed empowering the treasurer "to sell such of the securities of the institution as may from time to time be resolved upon by the committee for the purpose of defraying the outlays upon the works of the new buildings." It is earnestly to be hoped that such a step will never be necessary.

*Queen Victoria Jubilee Convalescent Home, Bristol.*

The annual report of this most useful institution states that in 1910 a record number of patients, 1983, were admitted. Of these, 687 came from the Royal Infirmary, 670 from the General Hospital, 28 from the Eye Hospital, 74 from the Bristol Dispensary, 19 from the Clifton Dispensary, while 338 were free patients admitted from various sources and 167 were paying patients. The income was £2883 15*s.* 10*d.*, the expenditure £2824 16*s.* 10*d.* It has been possible to allot two more beds each to the General Hospital and to the Royal Infirmary, each institution now having the use of 28 beds. Further, by the munificence of the late Mr. Enoch Hendy two more "free" beds have been endowed. Of the other beds specially allotted, the Eye Hospital and the Clifton Dispensary have one each and the Bristol Dispensary three. During the year the average stay of each patient has been 15 days, and the average increase in weight 3 pounds.

*The Winsley Sanatorium.*

The sixth annual report of this institution, presented at a recent board meeting by the chairman, Dr. R. Shingleton Smith, was very satisfactory. It showed that the daily average of patients is 65·7, and the total number admitted since the sanatorium was opened in 1904 is 1292. Of these, 85 per cent. have been improved to some extent, and 48·2 per cent. have gone out fit for some work. A linen league has been formed, under the presidency of Lady Hobhouse. The report of the finance committee is even more encouraging, for it shows that the institution is free from debt for the first time in its history, thanks mainly to the late Mrs. Procter Baber's munificent gift of £10,000. A balance remains in hand of £2122 4*s.* 3½*d.*, to be used as the nucleus of a fund for certain proposed extensions. The Manchester Unity of Oddfellows has undertaken the maintenance of two beds, and the total extinction of the mortgage debt has set the institution free from its heavy annual payment of interest on loan. The ordinary income has also increased from £5561 3*s.* 8*d.* in 1909 to £5838 7*s.* 6*d.*

*Bristol Medical Dramatic Society.*

A very creditable performance of Sir A. W. Pinero's farce, *The Schoolmistress*, has formed the annual outburst of energy for which the Bristol Medical Dramatic Society exists. The piece chosen was eminently suitable, and the cast proved equal to the occasion. The All Saints' Hall was well filled each evening from Feb. 21st to 25th. Mr. W. S. V. Stock as the Hon. Vere Quekett, Mr. J. C. Heaven as Admiral Ranklin, Mrs. F. W. Rogers as Miss Dyatt, and Miss Sylvia Heaven as Miss Hesslerigg are specially worthy of commendation. The proceeds will be devoted to the funds of the University athletic ground.

*The Bristol Coronership.*

Mr. H. G. Doggett, who has been coroner for Bristol since 1892, has resigned the appointment. His resignation will be regretted by the local members of the medical profession, to whom he was always most kind and courteous. The deputy coroner, a solicitor, is a candidate for the post, and the names of two other members of the legal profession are also mentioned. Up to the present there is only one medical candidate, who is also a barrister.

*Bristol Hospital Sunday Fund.*

The collections received up to date amount to £1600 9*s.* 7*d.*, and of this sum £1400 have been allotted as follows: Royal Infirmary, £609; General Hospital, £511; Children's Hospital, £189; Eye Hospital, £91, other sums going to various smaller institutions.

*The Royal Devon and Exeter Hospital.*

The annual meeting of the subscribers of the Royal Devon and Exeter Hospital was held on Feb. 16th. The medical report stated that during 1910 the in-patients numbered 1614, compared with 1585 in 1909. 5014 out-patients were treated, as against 5500 in the previous year. The average cost per occupied bed was £56 16*s.* 4*d.* per annum. The financial statement showed the ordinary income was £10,062, the expenditure £11,129, the deficit being £1067.

*The Exeter Dispensary.*

The annual meeting of the subscribers of the Exeter Dispensary was held on Feb. 22nd. The medical report stated that during 1910 the number of "recommends" used amounted to 5068, compared with 5003 in 1909. Since the opening of the dispensary in 1818 the patients treated amounted to 337,575. The financial statement showed that there was an adverse balance of £269 on the ordinary income of the year, but it was stated that the invested funds of the charity amounted to about £21,000.

*Exeter Sanatorium for Infectious Diseases.*

The annual report of the medical officers of the Exeter Sanatorium shows that during 1910, 296 cases were admitted; of these, 217 came from the city of Exeter and 79 from the county of Devon. There were 16 deaths, equal to a rate of 5·45 per 100 cases admitted. In 1909 the admissions were 361.

*British Red Cross Society.*

At a public meeting held recently at Axminster (Devon) it was decided to form a men's voluntary aid detachment, and Mr. John Neville Blithe Vise, L.R.C.P. Lond., M.R.C.S. Eng., was appointed commandant.

*The Care of the Feeble-minded.*

At its last meeting the Taunton board of guardians offered the workhouse, with the exception of the infirmary, as a suitable building for the accommodation of pauper idiots, imbeciles, and epileptics for the county of Somerset, and this offer will be conveyed to the various boards of guardians concerned.

*Royal West of England Sanatorium, Weston-super-Mare.*

The annual meeting of the subscribers to this institution was held on Feb. 18th. The medical report stated that during 1910 the patients admitted numbered 2322; of these 1143 were males and 1179 females. The financial statement

showed that the expenditure amounted to £4020, and that the receipts showed a falling off of £900 compared with the previous year. This decrease is due to the fact that during the past year the committee had admitted no cases of pulmonary tuberculosis, but it is hoped that more subscribers will come forward and that the usefulness of the sanatorium will be maintained.

*The Mortuary Accommodation at Falmouth.*

At a recent inquest held in Falmouth (Cornwall) the medical man who performed the necropsy complained to the coroner of the state of the mortuary. He stated that there was no water-supply, no proper table, and that the only light which could be obtained was through keeping the door open. He added that there were no towels or means of washing the hands. The coroner said that such a state of affairs was not a credit to Falmouth, and at the request of the jury he decided to draw the attention of the town council to the subject.

Feb. 28th.

## SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

*The Association for the Promotion of the Registration of Nurses in Scotland.*

AT the annual meeting of the Association for the Promotion of the Registration of Nurses in Scotland, held in the lecture theatre of the Royal Infirmary, Edinburgh, on Feb. 24th, the chair was occupied by Lord Inverclyde, the President of the association, who said that he was glad to acknowledge the increasing interest which nurses were taking in the work of the association. The various reports were unanimously adopted. Resolutions were passed approving the action of the executive during the year and reappointing the officers and executive for the coming year.

*Glasgow R.A.M.C. Officers' Dinner.*

The annual mess dinner of the officers of the Glasgow units of the Royal Army Medical Corps (Territorial Forces) was held last week. Sir George T. Beatson, K.C.B., Administrative Medical Officer of the Lowland Division, presided, and the company, which numbered over 100, included Surgeon-General W. L. Gubbins, C.B., Director-General of the Army Medical Service. The chairman, in the course of the evening, made a statement regarding the medical service of the Lowland Division. He indicated in the first place that the Territorial Medical Service had been framed on the same lines as that of the Regular Army. It consisted of sanitary and medical establishments of regiments; ambulances in the proportion of three to a division, with the cavalry ambulance for the mounted brigade; sanitary companies where they were thought necessary and water duty men; means for evacuating the sick and wounded from the field units to the general hospitals; general hospitals with staffs of physicians and surgeons from the large civil hospitals in the locality; convalescent homes; and a divisional staff for supervising and coördinating the above formations. As regarded regimental assistance in the Lowland Division, all the units with the exception of two had been provided for, but as each had two medical officers and only one would be called up on mobilisation, they would be quite able to fill up the deficiency. He was glad to say the field ambulances were at full strength in officers and men. They had not yet been called upon to form sanitary companies, but they had the full complement of water duty men, who had done duty during the past two seasons with their respective regimental units. The work of providing voluntary aid detachments for the rapid evacuation of the sick and wounded from the field ambulances to the general hospitals had been enthusiastically taken up in Scotland by the county committees of the Red Cross Society. It was gratifying to know also that the general hospitals were complete. They had obtained the surgical and medical staff and the nurses, and had practically settled upon the buildings, so that within the next ten days, if the consent of the director-general was obtained, they could have in Glasgow and Edinburgh three general hospitals giving 1560 beds in working order within 24 hours. In this connexion he acknowledged they had been met in a very generous and helpful spirit by the Poor-law authorities. Finally, as regarded convalescent homes, they would be arranged for through the Red Cross Society.

*Medical Inspection in Aberdeen and Increased Cleanliness of Children.*

Dr. G. Rose, medical officer of schools in Aberdeen, reports a marked improvement with regard to cleanliness between the children who applied for enrolment in January, as compared with the condition of those who sought admission in August. Of the 763 children examined one-fifth were found defective, the defects calling for exclusion being in 9 cases ringworm, in 5 impetigo, in 1 itch, in 8 vermin, and in 4 other affections. The expediency of excluding such cases on the first attempt to enter school was thus apparent.

*Tuberculosis in Aberdeen.*

Dr. Matthew Hay, medical officer of health of Aberdeen, states in his annual report that for the last few years he has been collecting information regarding the prevalence of tuberculosis in Aberdeen. In 1909 there were 181 deaths from pulmonary phthisis, and 89 deaths from other forms of tuberculosis. The mortality rate both from pulmonary and from other forms of tuberculosis was appreciably lower in Aberdeen than in any other of the large towns. In recent years nearly twice as many girls as boys have died from phthisis. Dr. Hay thinks it not unlikely that this is due in part to the more outdoor life led by boys. Under five, boys, more than girls, tend to be phthisical. Dr. Hay suggests that the high mortality from tuberculosis in infancy—whatever be the source of infection—is due to the low vital resistance or immunity characteristic of the first two or three years of child life. He does not desire to be understood as denying that infantile tuberculosis is due in part to bovine infection. The investigations of the English and German commissioners make it practically certain that infected cow's milk is a source of tuberculosis in infants and children; but the chief source, nevertheless, in them, as in adults, is human infection.

*Vaccination in Aberdeen: Interesting Figures.*

Dr. Hay also furnishes to one of the local papers interesting figures with regard to the vaccination of children in Aberdeen. In 1880, 99 per cent. of the children were successfully vaccinated; in 1890 the figure had fallen to 96 per cent., and in 1900 it was also 96; while in 1906—the year before the passing of the Act—the percentage was 90. In 1907, as a result of the concession to "conscientious objectors," the figure fell to 85 per cent. and in 1908 to 84 per cent., the percentage in 1909 being 85 per cent. In 1907, 2 per cent. of the children were not vaccinated on account of "conscientious objections." In 1908 the percentage was 5·5, and in 1909, 8·4. Since the introduction of the Act there has been a drop of 5 per cent. in the number of successfully vaccinated children in Aberdeen, and compared with 1900 a drop of 10 or 11 per cent.

*Diamond Wedding of an Orkney Doctor.*

On Feb. 20th Dr. and Mrs. Logie of Isbister, Orkney, celebrated the sixtieth anniversary of their wedding. Dr. Logie, who is in his ninety-first year, was for many years a medical practitioner in Kirkwall.

March 1st.

## IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

*Workhouse Inmates and Old Age Pensions.*

WHEN the pauper disqualification for pensions was removed, an old man who had been for years an inmate of the Swinford Workhouse took his discharge, and was awarded an old age pension. He then claimed admission to the infirmary as a paying patient, the cost of maintenance being a few pence less than the weekly pension. The local pensions committee brought the matter before the Local Government Board, which declared the old man entitled to his pension. His example is now being followed in other unions. In Claremorris the guardians have ordered the master of the workhouse to prepare claims for all the old people in the house on condition that they pay for their maintenance. The result should be a considerable relief to the rates, together with a small amount of pocket-money for the old people.

*Beri-beri in Galway.*

Last week three negroes of the crew of a barque which arrived in Galway from the West Coast of Africa were reported on the sick list. The port medical officer, Dr. W. A. Sandys, and the Local Government Board inspector, Sir J. Acheson McCullagh, diagnosed beri-beri, and the men were removed to the union fever hospital. It is not clear why the patients were not sent to the port isolation hospital. The presence of beri-beri in such an insanitary town as Galway is likely to cause some anxiety.

*Qualification for Inspectorship of Lunatics.*

Some time ago, in view of an expected vacancy in the office of inspector of lunatics, the claim was made that one of the two inspectors should be a woman. Now it is further suggested that one of them should be a "layman of experience" in business matters. The following resolution was passed last week by the Cork asylum committee:—

Whereas the lunatic asylums are in some degree hospitals for curable patients, but in the main homes for chronic inmates, and their upkeep costs the nation over half a million sterling per annum, and whereas there are extensive buildings, workshops, and machinery, lands, farming stock and implements, workmen of all classes, contractors for the supply of the most varied commodities, large numbers of inmates, whose work can be applied reproductively, and other important concerns of a purely business nature, we are strongly of opinon that one of the inspectors of lunatics should be an expert in mental diseases and that the other should be a layman; and that in the interests of the sound and economic working of asylums we respectfully request the Lord Lieutenant to appoint to the post of second inspector, now about to become vacant, a layman of much business ability and experience, of strong grasp of finance, and of great power of organisation, and that copies of this resolution be forwarded to the asylum committees of Ireland.

*Visit of H.R.H. the Princess Christian to a Dublin Hospital.*

H.R.H. the Princess Christian visited last week the Royal City of Dublin Hospital. Her Royal Highness has continuously manifested her interest in this institution since she laid the foundation-stone of its nurses' home in 1900.

*How Dublin's Poor Live.*

At the annual dinner of the Royal Institute of Architects held in Dublin on Feb. 25th, the Lord Lieutenant said that the last census showed that one-fourth of the entire population of Dublin lived in one-roomed tenements, and more than 8 out of every 100 tenements of all kinds were one-room tenements having five or more occupants. This proportion showed twice as many such tenements as in Glasgow, compared with the population of that city, nearly four times as many as in Edinburgh, and 32 times as many as in Liverpool. The excess of such tenements as compared with Belfast was even greater, and still more so as compared with Manchester, where such one-room tenements were only a small fraction of the whole. Again, if they took the number of people who lived in one-room tenements (with five or more occupants) they found that in Dublin the number was 1061 out of every 10,000 of the population; in Glasgow 524, Edinburgh 233, London 70, Liverpool 24, Belfast 10, and Manchester 5. His Excellency quoted Sir Charles Cameron, medical officer of health of Dublin, as follows: "It is the large proportion of the one- and two-room tenements in Dublin which reacts so injuriously on the death-rate of the whole population." Lord Aberdeen spoke of the moral effects of life in such conditions, and said the marvel was that there was not a great deal more vice and crime. He strongly urged the providing of healthful dwellings for the people.

*Londonderry Infirmary.*

Mr. Walter Bernard, physician to the Londonderry Infirmary, has felt called upon to resign his position, owing to failing health. It has been decided to call a special meeting to discuss the terms of appointment of the honorary medical staff. In an institution in which it was reported that on Feb. 21st there were 56 in-patients as well as a good-sized extern department, there is room for physicians, surgeons, and specialists.

*Death of Mr. William Leatham, M.A. T.C.D., L.R.C.S. Irel., J.P.*

Mr. William Leatham, one of the oldest and best-known medical practitioners in County Tyrone, died at his residence, Lisdhu, Dungannon, on Feb. 20th, at the advanced age of 73 years. Mr. Leatham was an M.A. of Trinity College, Dublin, and in 1860 became an L.R.C.S. Irel. He practised for 40 years in the Coalisland district, where, until a few years ago, he was dispensary medical officer. He was medical attendant to the Royal Irish Constabulary and also a certifying factory surgeon. During a long professional career Mr. Leatham enjoyed very fully the confidence and esteem of all classes and creeds.

*Diphtheria in Rathfriland.*

An epidemic of diphtheria has broken out in Rathfriland, County Down, and the surrounding district. The public schools have all been closed. Several cases have been sent to Newry Hospital, and the authorities are doing everything to grapple with the serious situation that has developed.

*The Samaritan Hospital, Belfast.*

The medical report presented at the annual meeting of the Samaritan Hospital, Belfast, on Feb. 27th, showed that during the past year there were 589 extern and 245 intern patients. Of these 222 required surgical operation, 79 of them being major operations. The in-patients and operations performed were more numerous than in any previous year. Financially the amount of debt at the end of the year was close on £470.

Feb. 28th.

## PARIS.

(FROM OUR OWN CORRESPONDENT.)

*Treatment of Fracture of the Wrist.*

AT a meeting of the Academy of Medicine held on Feb. 14th M. Lucas-Championnière presented a memoir by M. Marbaix giving details of the treatment of a number of cases of fracture of the wrist. In this memoir M. Marbaix showed the advantages of massage and immediate mobilisation which he had practised in the most thorough manner. He said that after immobilisation of the injured part in the orthodox plaster apparatus the average interval before the patient returned to work was 200 days, but this period was reduced to 40 days when massage and mobilisation were employed.

*The Teaching of "Puériculture."*

At the same meeting M. Pinard made an important communication on the subject of puériculture, and as a type of this means of contributing to the preservation of the race he instanced the Pouponnière, an admirable institution at Porchefontaine, most ably conducted by Madame Veil-Picard and Dr. Raimondi. Single young women who had become mothers were received there with their infants and were provided with a home in return for the services which they gave as wet nurses in the institution. The premises included an infirmary and a model cowhouse, in which the cows were managed so that their milk could be used without being boiled. Among 1946 infants admitted during the last ten years there had been only 54 deaths. Opportunities for the teaching of puériculture are provided. At Porchefontaine the pupils of the normal school of Versailles and those of Sèvres receive practical instruction. M. Pinard was of opinion that in every town in France where there was a normal school for girls there ought to be an institution for puériculture in connexion with it.

*The Mortality of Adults in France.*

The death-rate commission, which is officially subordinate to the Ministry of the Interior and has for its president Professor Lannelongue, a member of the Senate, has adopted the conclusions contained in the report by Professor Lannelongue and Dr. A. J. Martin on the mortality of adults in France. After pointing out that this mortality is steadily declining in France, the report states that this decline is due to the increased attention paid to public hygiene, to the sanitation of towns and houses, and to the personal care of health. The mortality due to transmissible and preventable diseases is continually becoming less, with the single exception that the mortality from tuberculosis either remains stationary or even increases a little, and is responsible for one-fifth, and sometimes even for one-fourth of the total mortality. It is, therefore, in the opinion of the commission, urgently necessary to take all requisite measures for reducing this serious danger to life. For this purpose endeavours should be made to stop the progress of alcoholism, and to encourage whatever tends to the prevention of tuberculosis, including precautionary measures due to individual initiative. It is especially necessary that tuberculous disease should be recognised at the first appearance of the symptoms. The patients in this early stage should receive appropriate treatment, should be prevented from becoming a danger to others, and should have their

necessities provided for as long as they required to be kept under observation.

*Leprosy.*

A commission was some time ago appointed by the Société de Pathologie Exotique for the purpose of reporting on the prevention of leprosy in France. The report has now been presented, and recommends (1) the inclusion of leprosy among the diseases which are compulsorily notifiable in France; (2) the maintenance of a discreet supervision over lepers in order that infected children may be prevented from attending the ordinary schools and adults prevented from following certain occupations; (3) the hospital treatment of leprous beggars and destitute persons; (4) the encouragement of private sanatoriums; and (5) diplomatic arrangements with countries where leprosy prevails in order to prevent the migration of foreign lepers into France.

*The Prevention of Plague.*

An international sanitary conference will be held in Paris next May. In order to facilitate its proceedings the subjects of discussion will be arranged by the permanent committee of the international office of public hygiene, and as soon as the committee has considered these questions its conclusions will be communicated to all the governments invited to take part in the conference.

*Action for Damages against Medical Men.*

A man who had had his face, arms, scalp, and back completely covered with tattoo marks at last became anxious to have them removed and for this purpose he sought advice at the Hôpital Beaujon. Dr. Bazy of that hospital recommended treatment by air heated to a temperature of 800° C. and referred the applicant to Dr. Vignat, who undertook the case and applied the treatment successfully as regards the man's face. On the fingers being afterwards subjected to a similar process the man alleged that the hot-air treatment caused stiffness of his finger-joints and brought an action against Dr. Bazy and Dr. Vignat claiming 6000 francs as damages. These gentlemen, however, cited the man before the *tribunal des référés* on the ground that it was necessary to have him immediately examined by a surgical expert because he was keeping his fingers perfectly immoveable and this might in course of time have the effect of causing stiffness of their joints. They also maintained that it would be useful to have precise information as to the condition of the man's fingers from the present time until the date of the trial.

*Attempted Simulation of Pyrexia.*

For several months past much interest has been aroused in France by the trial of Dr. Brengues, who is accused of having murdered his brother-in-law, an astronomer, in order that he might inherit the property of the deceased. At the present time the case is under consideration by the assize court of Nice. Dr. Brengues having represented that he was in bad health three medical experts were appointed to investigate his symptoms. After hearing the statements of the accused, who said that he suffered from several serious disorders, the experts made a preliminary examination and went away, directing the chief warder to take the temperature of the accused at 6 P.M. When this time arrived the warder telephoned to one of the experts stating that after he had placed the thermometer in position he went away for a few moments, and on his return was astonished to find that a prisoner who shared the cell with Dr. Brengues was warming the thermometer over the gas jet, and that it showed a temperature of 42·8° C. The expert then proceeded to the prison, where he noted that the pulse of the accused was regular and making 80 beats per minute; the thermometer in the axilla showed a temperature of 38° C., whilst another one placed in the rectum showed 37·2°. Both thermometers were then placed in the rectum, when the one registered 37·2° and the other 37·4°. The case was therefore an instance of attempted malingering.

*Monument to Professor Cornil.*

A monument in memory of Professor Cornil will be unveiled on Sunday, March 5th, at 10.30 A.M., at the École Pratique of the Paris Faculty of Medicine. The President of the Republic will preside at the ceremony. The monument has a fine appearance, and is the work of Dr. Paul Richer, a member of the Academy of the Fine Arts and of the Academy of Medicine.

Feb. 27th.

# VIENNA.

(FROM OUR OWN CORRESPONDENT.)

*Remarkable Cases of Swallowing Foreign Bodies.*

A SUICIDAL inmate of a lunatic asylum in Vienna swallowed several spoons and forks, which he had purposely broken across, but singularly enough no appreciable ill effects were produced. He was subsequently discharged and was able to do hard work as a labourer for two months, after which he began to suffer from hæmorrhage from the mouth. This was at first supposed to be of pulmonary origin, but when an examination by a surgeon proved that the blood came from the stomach he was admitted into a surgical ward and operated upon by Dr. Rotheissen, who showed the case at a meeting of the Gesellschaft der Aerzte. Before the operation no foreign body was palpable in the abdomen when the patient was in the reclining posture. The X rays showed near the vertebral column a dark shadow which sank into the pelvic space when the man was standing, and the foreign bodies could then be felt by the hands. When the abdomen was opened the stomach was found to be hypertrophied; the pyloric part was open. A small incision made it possible to extract 14 broken spoons and their handles. There was no gross lesion of the mucous membranes except a condition of chronic catarrh, and the recovery was uneventful. In the case of another patient on whom an operation was performed a short time ago the contents of the stomach had led to perforation of its walls causing peritonitis. The operation revealed the presence of 42 nails which he had swallowed during an attack of melancholia; one of them had worked its way through the wall of the pyloric part, injuring the serosa, whilst the others had already passed the pylorus and lay in the duodenum at a place which was very difficult of access, and as the patient seemed to be in a desperate condition they were left undisturbed and eventually passed out by the anus. It was afterwards ascertained that a month previously the patient had swallowed 10 tacks, which also had passed through his bowels without producing any harm. Both patients are at present doing well.

*Precautions against Plague: End of the Cholera Quarantine.*

The westward progress of plague along the Siberian railway and the possibility of its conveyance by shipping were discussed at the last meeting of the Austrian chief Board of Health (Oberste Sanitätsrath). At present there is no cause for alarm in this country, but the medical officers of health on the eastern frontier as well as in the Adriatic ports have nevertheless been requested to use the utmost vigilance. A quarantine of eight days has been ordered for all arrivals from suspected districts. There was an outbreak of plague in Vienna some ten years ago, when a plate culture containing plague bacilli was scattered in the midst of several persons in one of the laboratories of the General Hospital. At that time Dr. Müller, who had been one of the members of the Austrian plague commission sent to India for the purpose of studying the disease, volunteered to attend the infected persons, two of whom died, as well as Dr. Müller himself from the same cause, but the outbreak spread no further. This prompt success was due to the adoption of most stringent measures, and there is every reason to hope that any fresh invasion could be similarly overcome. As there have been no cases of cholera in Hungary for more than two months, Austria and Hungary have now been officially declared to be free from this disease, and no special precautions are being taken with regard to it.

*Death of Professor Gustav von Braun.*

Some days ago Professor Gustav von Braun, the senior of the Vienna gynæcologists, died at the ripe age of 82 years after a short illness. He was really a self-made man, who by sheer force of talent had attained a most successful practice among the upper class of the population, whilst he at the same time filled until 10 years ago the post of director of the obstetric clinic for midwives in Vienna. He was one of the first to recognise the importance of Semmelweis's observations relative to puerperal infection, and when the era of antisepsis and asepsis arrived he was quick to adopt these new departures as soon as their utility was proved. It is in great part due to him that the Austrian midwives are capable of using modern methods in the treatment of

parturient women, for he organised the teaching of midwives in a most efficient manner. He worked a good deal on certain problems connected with his specialty, especially on anomalies of the pelvis, on extra-uterine pregnancy, and on obstetric surgery. When circumstances required he used to deliver lectures and hold classes in the French, English, and Italian languages for the convenience of the numerous foreign students who come to the University of Vienna.

*Death of Professor Escherich.*

Professor Escherich, the celebrated specialist for diseases of children, died on Feb. 15th, after an illness of only two days. While visiting the wards of his clinic the day before his death he mentioned that he did not feel quite in his usual health. Suddenly he began to speak in different languages, his mind wandered, and he had to be conveyed to his home, where he died the next day. An acute exacerbation of arteriosclerosis from which he suffered was brought on by exertion and abruptly terminated his brilliant career. He was born 54 years ago, and after graduating at a comparatively early age he was soon attracted to the study of children's diseases. While still a young man he obtained a high reputation as a keen observer and an excellent teacher; his first appointment as an independent director of a clinic was in Munich, whence he was called to Graz. In 1902, when Professor von Widerhofer died, he was appointed professor of pædiatrics in Vienna. Here he soon created a special school, which energetically followed up the problems of combating the mortality of infants by scientific and social work. The chemistry and bacteriology of early life were the leading features of the clinical research carried on under his supervision, and numerous contributions to science have originated or were inspired in his clinic, the staff of which always included proficients in various departments of investigation. Professor Escherich's chief published works were "The Bacteria of the Intestines of the Infant," "Diphtheria and Serotherapeutics," and "Tetania."

Feb. 27th.

## CANADA.

(FROM OUR OWN CORRESPONDENT.)

*Annual Dinner of McGill Medical Students.*

AT the annual dinner of the McGill medical students, held in Montreal on the evening of Feb. 2nd, Dr. R. Tait McKenzie, professor of physical education at the University of Pennsylvania, Philadelphia, U.S.A., was the guest of honour. Mr. Roy McGibbon, president of the dinner committee, occupied the chair, and seated at the head table were Principal Peterson, Dean F. J. Shepherd, Registrar J. W. Scane, Judge Archibald, Professor H. S. Birkett, Professor W. F. Hamilton, Professor A. E. Garrow, Professor J. C. Cameron, Professor Nichols, and Dr. Andrew Macphail. Representatives from Toronto, Queen's (Kingston), and Laval (Quebec) failed to be present, being snow-bound on account of the severe blizzard raging that day. Dr. Tait McKenzie spoke of the physical education of the city dweller and said that the whole ground of medical teaching was changing with the life of the people. To-day there are 60 per cent. of the civilised people living in cities. Physical education is the study of the most vital problem facing modern nations. It was the constructive side of medicine. A letter was read at the gathering which went to show that $10,000 had been subscribed as a memorial fund to the late Dr. Arthur A. Browne, and that the committee in charge of it had decided to found a scholarship at McGill to be known as the Arthur A. Browne Scholarship. Dr. T. G. Roddick wrote that he was unable to be present, but sent the students encouraging news with regard to Dominion registration. He confidently expected that in the course of a few days the Canadian Parliament would have passed the amendment to the Canada Medical Act of 1902, which, when ratified by the nine provincial legislatures, would give Canadian students of medicine the right on graduation to commence practice in any province they pleased without further examination. This amendment has recently been considered by a special committee of the House of Commons, but it did not pass unanimously in its entirety, as representatives from the province of Saskatchewan, where there is no university and no medical school, objected to the university representation clause.

*Notre Dame Hospital, Montreal.*

During the year 1910 over 2500 patients were admitted to Notre Dame Hospital, Montreal; in 1909 there were 2215. Out of the 2500 admitted over 2000 were discharged absolutely cured. During the whole year there were 104 deaths in the institution. Some were left in the institution at the end of the year and the balance went out incurable. The ambulance calls numbered 1058. The month of December was the heaviest month. There were 21 deaths, 15 of which occurred within one hour after admission. A judgment has recently been rendered in Montreal of interest to the medical profession in connexion with this hospital. The complainant was a man whose wife had been admitted to the hospital with an injured ankle. When examined the injury was found to be a sprain. After a few days' rest in bed she was ordered to get up, which she did under protest and then fell upon the hospital floor, this time sustaining a fracture of the wrist. Action was entered for $625 damages on the ground that the woman had received additional injury in the hospital through carelessness of her attendants. The court held that the attendants had done all that was scientifically possible for the woman and judgment was rendered for the defendants.

*Poliomyelitis Infection from Canada.*

Dr. Eugene H. Porter, Commissioner of Health for New York State, is arranging with the Canadian authorities for an interchange of information and an agreement as to quarantine regarding poliomyelitis between the Province of Ontario and the State of New York. The disease has been prevalent to some extent along the Niagara frontier.

*Reciprocity in Medical Teaching.*

The medical faculties of Toronto and McGill Universities have entered into an agreement to accept each other's examinations up to and including that of the fifth year. When any student leaves either university with a clean bill of health, both academic and moral, he shall be awarded the same standing in either university without further examination. He could spend one year in Toronto, the second in McGill, and so forth. This signifies that for the future the two medical faculties will act as one in the matter of medical standards. It will tend towards uniformity in standards of matriculation, curricula, and examinations. If these two leading universities be supported by the other universities of Canada in this agreement there will be a tendency to revision and elevation of medical standards all over the Dominion.

*Caisson Disease in Canada.*

Dr. P. Conroy of Charlottetown, P.E.I., who for three years was medical attendant upon several hundred caisson workers employed in constructing a large bridge near or at Charlottetown, gained thereby an opportunity to study caisson disease at first hand. An interesting point elicited by Dr. Conroy, and duly chronicled in a paper in the *Maritime Medical News*, was that the workers themselves by their own practical experience had learned the best treatment. When the disease develops in a workman his comrades quickly take charge of him. He is immediately placed in a hot bath, rubbed vigorously, and then kept absolutely quiet in a hot room for several hours until convalescent. Dr. Conroy suggests that the disease is due to a toxæmia, and that its treatment by the workmen produces free perspiration as a safeguard.

*Medical Inspection of Schools in Canada.*

Medical inspection of schools in Canada has been in vogue to some extent for four or five years in Montreal, Halifax, Hamilton, Ottawa, Vancouver, and latterly in Toronto. Last year the Toronto Board of Education gave it a tentative trial, employing two inspectors and appropriating $2500 for the work. The work this year is to be on a more extended scale in Toronto. A chief medical inspector of schools has just been appointed in the person of Dr. E. W. Struthers at a salary of $2500 per annum. He is to have eight medical inspectors and a corps of nurses numbering 17 and a chief nurse. The total appropriation set apart for this work will reach $24,000. The Board of Education decided to retain control over the inspection work and not to delegate it to the medical health department of the city. In Halifax one general inspector and an oculist are employed with a few nurses. In Montreal the work is under the health department, with 17 medical inspectors at a yearly salary of $1200.

Vancouver works under a system responsible to its Board of Education.

*Stamping Out the Drug Habit in Canada.*

The Federal Government is considering legislation looking to control and to forbid under severe penalties the importation, manufacture, sale, or use of opium, morphine, and cocaine for other than scientific medicinal purposes. Other habit-forming drugs will probably be included in the measure. 12 to 15 per cent. of all the young people in the penitentiaries of Canada attribute their downfall to drugs, and it is authoritatively stated by the Dominion parole officer that, if a complete census were made, fully 25 per cent. would be more correct. During the last six months the police of Montreal have made 125 arrests of persons selling or using cocaine. The measure is strongly supported by the Canadian Pharmaceutical Association. The Quebec Government is also moving along similar lines. The Dominion Parliament will also enact legislation looking to the prohibition of the use of white phosphorus in the manufacture of matchmaking.

*New Board of Health for Ontario.*

The Ontario Government has just appointed a new board of health for that province. Dr. Adam H. Wright, Toronto, has been appointed chairman, to succeed Dr. Charles Sheard, whose term of office expired Dec. 31st, 1910. The other members of the board will be Dr. D. B. Bentley, Sarnia; Dr. James Roberts, Hamilton; Dr. George Clinton, Belleville; Dr. W. H. Howey, Sudbury; and Dr. J. W. S. McCullough, Toronto, the only member of the old board to be appointed. Dr. McCullough, who succeeded Dr. Charles A. Hodgetts a few months ago, will be chief health officer for the Province and secretary of the board.

*Toronto University and Medical Licences in Ontario.*

Dean C. K. Clarke, M.D., of the medical department of the University of Toronto, has thrown a bombshell into the camp of the Ontario Medical Council. In the report of the Board of Governors of the University to the Ontario Government there are set out the reasons, according to Dr. Clarke, why the Ontario Government should take away from the Ontario Medical Council the right to fix standards of medical matriculation, curricula, and to conduct examinations. He calls for a revision of the Ontario Medical Act whereby a student in medicine upon graduation would receive at the same time he receives his degree his licence to practise in the Province of Ontario without further examination by the Ontario Medical Council. Dr. Clarke claims that the Council hampers the University in promoting better educational facilities and setting higher standards for matriculation and examinations. He considers that it is not the function of the Council to set standards, conduct examinations, but to protect the general public from quacks and dishonourable and criminal practitioners.

*Reorganising Toronto's Health Department.*

Dr. Charles J. C. Hastings, recently appointed medical health officer of Toronto, has a comprehensive scheme of reorganisation of the health department of Toronto. Dr. Hastings estimates the expenditure for his department for 1911 at $159,000, which is $67,000 more than was spent in 1910. Mr. George Nasmith has been placed at the head of the laboratory and Dr. F. J. Hazlewood is to superintend the isolation hospital.

*Manitoba Medical College.*

The Faculty of the Medical College of Manitoba have decided to withdraw their offer of turning the college over to the University of Manitoba as a medical department. It is stated that this could not be carried out until the College first got the consent of the general profession in Manitoba, as the college only holds the property in trust.

Toronto, Feb. 16th.

UNITED SERVICES MEDICAL SOCIETY.—The next meeting of the above-named society will be held at the Royal Army Medical College, Grosvenor-road, S.W., on Wednesday, March 8th, at 5 P.M., when papers will be read by Lieutenant-Colonel P. J. Freyer, I.M.S. (retired), on "The Symptoms and Modern Methods of Diagnosis of Stone in the Kidney, Ureter and Bladder," and by Colonel H. Hathaway, A.M.S., on "Ambulance Transport."

# MEDICAL INSPECTION AND TREATMENT OF LONDON SCHOOL CHILDREN.

*Proposals for Reorganisation.*

THE report to the Education Committee of the County Council on the re-organisation of medical inspection and treatment in London, referred to in a leading article in THE LANCET last week (p. 514) was duly presented by the Children's Care Subcommittee at the meeting on Feb. 22nd. Owing, however, to pressure of business the consideration of the matter was adjourned until March 1st. As our article indicated, the report of the subcommittee took the form of an elaborate argument in favour of placing the work at present under the direction of the medical officer for education, Dr. J. Kerr, definitely under the supervision of the education officer, Mr. R. Blair.

The subcommittee, first defining the present position, pointed out that the Acts under which medical inspection and treatment were carried out were administered by the Board of Education and the duties the Acts enforced or legalised were imposed on the Council as local education authority. The Council's medical work was carried out by officers whose entire duties were concerned with the administration of education. As regards medical inspection, the whole of the work—administrative as well as professional—was carried out by Dr. Kerr. He was technically an officer in the public health department of which the chief officer was Sir Shirley Murphy, but Dr. Kerr had enjoyed a large measure of independence and had had delegated to him expressly by the Council the exercise of the duties of school medical officer under the regulations of the Board of Education. The arrangements for medical treatment were carried out by the education officer, Mr. Blair, as part of the general machinery of educational administration. As soon as a school medical officer, after inspection of a school, had reported that certain children required treatment the necessary action for securing it was taken (1) by the children's care committees of the different schools, and (2) by the central office staff of the education officer's department, who made appointments for the children at the hospitals and medical treatment centres and saw to it that the arrangements were carried out in accordance with the conditions laid down in the agreements.

*Need for Unification.*

This division of the work between two different departments of the education service had had an injurious effect, in the opinion of the subcommittee, upon the working of the Council's scheme. It was of the greatest importance that the arrangements for medical treatment should be closely associated with those for medical inspection, and from the experience gained during the past year the subcommittee had come to the conclusion that the whole of the administration should be entrusted to one department. This unification might be effected in one of two ways—

(1) The whole of the work might be entrusted to Sir Shirley Murphy, Dr. Kerr being definitely placed under his control and made responsible to him both on the professional and the administrative side.

(2) The whole of the work might be placed under the control of Mr. Blair, the education officer, Dr. Kerr being placed in his department and made responsible to him on the administrative side, while retaining an independent position so far as expert medical advice was concerned.

In support of the view that the work should be placed under the Council's medical officer of health, the memorandum of the Board of Education, dated Nov. 22nd, 1907, might be quoted. It stated that the medical inspection and treatment of school children should be carried out in intimate conjunction with the public health authorities under the direct supervision of the medical officer of health of the authority which appointed the education committee. The policy suggested by the Board could be carried out readily in county boroughs where the medical officer of health was under the jurisdiction of the same authority as that which was responsible for education, but there would be great difficulty in applying the policy to London, where there were 29 officers of health responsible to 29 different authorities, while education was under the control of one central authority. True, the County Council had been entrusted by Parliament with powers of supervision and control over certain general matters of public health which did not fall within the scope of the borough

in many ways was very great. Formerly, at home, he had practically eaten nothing and cared only to stay in bed. He now ate and drank all that was given him, and was always ready to rise from bed in the afternoon. After six days his blood count was as follows: Red corpuscles, 5,100,000 per c.mm., or 102 per cent.; white corpuscles, 3000 per c.mm. The general improvement was, however, not maintained. He had to return home, and gradually the disease obtained the upper hand.

Pernicious anæmia, of course, shows remarkable remissions, but the rapid improvement in the blood count after the hypodermic treatment seems to hold out some hope for the cases of younger and more vigorous patients, especially if it were begun soon enough. I did not see my patient until the case was at least four months advanced according to history, and quite possibly more.—I am, Sir, yours faithfully,

East Meon, Hants, February, 1911. EDWARD T. JONES.

# EXPERIMENTS IN SEWER VENTILATION AT LEICESTER.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

Leicester, February, 1911.

MORE than eight years have elapsed since a detailed description was given of an ideal method of ventilating sewers.[1] At that time the system had not gone beyond the theoretical and laboratory stage. The chief fault then found was that it all seemed too good to be true. Now it is possible to speak differently, for the method has been applied during a sufficient number of years and to a large enough district to be judged from the practical results obtained. The object of the system is to prevent the ventilation of sewers in the streets or by soil-pipes on the tops of the houses. Further, greater care is displayed to prevent the intercepting traps placed between houses and sewers becoming small cesspools and to ensure more efficient ventilation of the small branch drains. A vigorous current of air may pass along the straight sewer in the street and yet have but little or no effect on the small tributary drains that come from behind the houses and down passages. The only way to ensure ventilation throughout is to place the inlets or outlets at the extreme ends of the piping. Thus there is the school of sanitary engineering that would have no intercepting trap between the house and the sewer, and by carrying every soil-pipe to the roof of the houses convert them all into sewer ventilators. The air would then have to travel the whole length of the domestic drains to get out, and there would be no neglected corners or branch drains. The ventilation of private drains and public sewers on the roofs of dwelling houses and within a few feet of bedroom windows is not, however, a very satisfactory expedient. To say that the sewer air will be blown away is not a sufficient assurance. When a neighbouring chimney catches fire the odour, and even the smoke, is blown down to the street level. Sometimes the smoke from one chimney is blown down the chimney of another house, invading, much to the surprise of the inhabitants, a room which has no fire; and where the smoke goes the air from the soil-pipes will follow.

### *Air Needed Per Head in Sewers.*

To meet these and many other objections it has been proposed to reverse the process and not allow any air to escape from the soil-pipes; but, on the contrary, to draw air down these pipes to the domestic drains and into the sewers. Here the air would be conveyed to a spot where it could be treated or safely discharged. For this artificial power is necessary, and that constitutes the first and probably the chief objection to the whole system. There is an instinctive dislike to the employment of machinery, based probably on the too frequent experience that machinery is apt to get out of order. It is therefore a good point in favour of a mechanical system if it can be shown that, in the event of a breakdown in the machinery, no very injurious consequences would ensue. Of greater importance than arguments for or against machinery is the dominating fact that in ventilating it is absolutely impossible to ensure a stable result except by the use of machinery. Just as the weather varies, so does natural ventilation vary, and this precisely in the opposite direction to our requirements, giving violent draughts in cold weather and hardly any movement of the air when it is hot and sultry. In dealing with this problem Mr. I. Shone had the advantage of experience as a mining engineer, where the entire ventilation must be artificial, though the breakdown of machinery might involve a serious loss of life. There was no hesitation, therefore, in proposing to base the ventilation of sewers on the revolutions of a fan so as to provide in all weathers exactly the volume of air required to keep the atmosphere within the sewers and drains so fresh as to be uninjurious. What this amount would be has been explained by others writing on this subject. Dr. Letheby had made experiments on the gases engendered by putrid sewage, and the results were that one cubic foot of fresh air every two minutes would suffice to dilute the air escaping from the 30 gallons, or normal daily flow of sewage per inhabitant. In other words, for every inhabitant 30 cubic feet of fresh air must be drawn every hour into the soil-pipe of the house inhabited. Obviously this cannot be done with any degree of certainty except by mechanical appliances. Having obtained this figure it was further possible to calculate that at 3*d.* per Board of Trade electric unit a "Sirocco" fan could be worked so as to provide the requisite amount of air for 1·41*d.* per annum per head of the population.

### *The Need of Cubic Measurements.*

The next point was to devise means to insure that the regulation amount of air should penetrate every soil-pipe, whether near or far from the fan. This seemed more easy to do in theory than in practice, and experience has proved the accuracy of this criticism. Originally a very elaborate inlet was provided, regulated by a vulcanite screw plug which had a small hole pierced in the centre. The size of the hole, in some places barely big enough to let a lead pencil through, varied according to the suction within the pipe, being smaller the nearer the house stood to the extraction fan. These and many other details were given by me in the first description of the system which appeared in these columns, and it is not necessary to go over the same ground again. But we have to see how far the original plan has been modified in actual application. That such experience has now been acquired is due to the enterprising spirit of the highway and sewerage committee of the Leicester Corporation. They determined to apply the system to an area of two and a half acres consisting of streets 40 feet wide with 80 six-roomed houses of the artisan class, and a population of 356 persons, or an average of 4·45 persons per house. The foul water sewers it was proposed to ventilate were 297 yards long. There is a totally separate system for storm and rain water from the surface of the streets and the roof of the houses. To convey the sewage proper there is a 12 inch pipe sewer 202 yards long and two short branches at right angles. The sewers to which the new system is applied discharge into a brick main of 3 by 2 feet, from which they are disconnected. At the junction the pipe sewer is carefully separated from the main sewer by a deep dip trap. The drains that connect the dwellings with the 297 yards of pipe sewers measure in all about 583 yards and are mostly 6 inches in diameter, while the branches to the closets and sink wastes are 4 inches. The smaller half of these have clay puddle joints instead of Portland cement for the joints. A 4 inch diameter cast iron pipe is added to the soil pipe and carried to the roof. It becomes a ventilator, but there are only 27 such ventilators to the 80 houses, in some cases six houses being connected with the one upright pipe ventilator. The cubic capacity of all these house pipes and drains is 304 cubic feet, that of the public sewer 661 cubic feet, so we have to deal with a total of 965 cubic feet, and it would take 6021 gallons to fill this with water. Now when a part of these drains and sewers were submitted to a water test it became apparent that there was a considerable leakage, amounting to seven gallons per minute. Here, then, was the first obstacle, the first great difference between the theory as demonstrated by laboratory experiments and actual application.

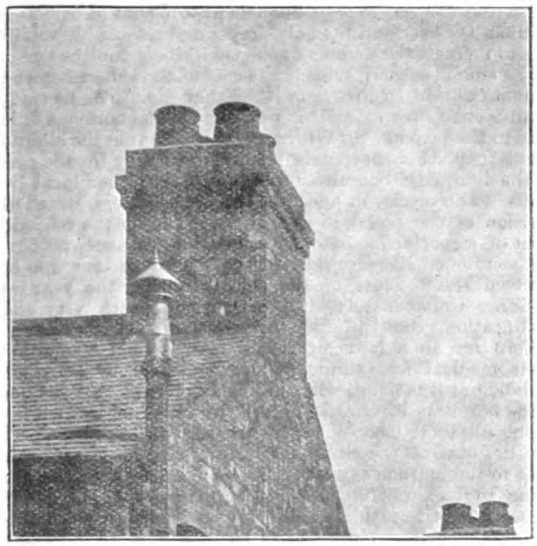
### *Leakage Upsets all the Calculations.*

At the highest point in the district a chamber was constructed under the causeway and here a "Sirocco" fan, 15 inches in diameter, driven by an electric motor capable of producing 700 revolutions per minute, was introduced. On one

[1] See THE LANCET, August 9th, 1902, p. 405.

side the chamber is connected with a flushing manhole and the air is drawn out of the sewer by the fan. On the other side the air thus extracted is forced into a ventilating shaft 40 feet high. When all was completed a five days' test was made. The velocity of the air entering the 27 soil-pipe inlets was measured by anemometers and the result showed that more air was pumped out through the extract ventilating shaft than had entered the sewers by the proper inlets. Therefore the leakage which had enabled some of the water to escape when the water test was applied now allowed some air to penetrate the sewers and drains. Thus the ideal calculations which, as said before, were all too good to be true are now upset. Given absolutely air-tight sewers and drains, with inlets all accurately measured and a fan revolving with mathematical precision, every soil-pipe would have received exactly the number of cubic feet of fresh air needed. But here was an unknown volume of air penetrating from unknown places and upsetting all these precise calculations. The mechanical part alone worked satisfactorily. The fan pumped out of the sewer exactly the right amount of air, only it did not appear that this air came from the farthest as well as the nearest inlets. At these inlets—that is to say, at the top of the 27 soil-pipes which are prolonged to the roofs of the houses—it was found, in some instances, that there was no perceptible current of air. It is true that air must travel at the rate of 30 feet per minute before it has sufficient force to move the anemometer, but the amount entering at a slower rate than this is hardly worth including in any calculation.

FIG. 1.



A cowl, constituting an air-inlet, placed on the top of the soil-pipes. The door-like opening can be seen which is used for introducing the anemometer.

Under the existing circumstances, short of re-laying all the house drains and the sewers in such a manner as to make them absolutely air-tight and keeping them in that condition for ever, a totally new set of calculations had to be made. Nor could any theoretical basis for such a reckoning be found, for no one could tell the extent of the leakages with which it was necessary to deal. Therefore, experiments had to be made with all the air inlets. Obviously much more air must be extracted so as to maintain a current through all the soil-pipes and also carry away what the leakages supplied. The minute and elaborated air inlet was too delicate an instrument for this rougher procedure. After trying many models the present system was adopted. It consists of a cylinder fitting over another cylinder. Both these have vertical apertures or slits, and the outer cylinder can be twisted round. If the apertures are made to fit over each other we have the maximum opening, but by slightly moving the outer cylinder the openings are rendered smaller and smaller till they are closed altogether. This is covered over by an ornamental hood or cowl to keep the rain off (Fig. 1). Underneath there is a commencement of piping which fits on the top of the soil-pipe, and here is the space for a small door large enough to admit a hand holding an anemometer. Thus it is necessary to place a ladder against the wall, to climb up and introduce an anemometer into this aperture. If the record shows that the amount of air descending the soil-pipe is insufficient, then the cylinder above must be turned round so as to enlarge the inlets. This descent of the air will vary from soil-pipe to soil-pipe according to its position and proximity to the extraction fan. Thus there is no rule, but a separate experiment must be made in each instance. This may seem complicated, but the needful procedure shows that the system deals with realities. According to the experiments made and the report of the borough engineer, Mr. E. George Mawbey, M.Inst.C.E., the 27 inlets measured at first only 10,278 square inches, and this might have sufficed had the sewers been absolutely air-tight. The inlets had to be increased to 75,258 square inches, and the six-inch diameter extraction shaft was replaced by a nine-inch pipe. Thus the inlet space was equal to 89 per cent. of the outlet space given by the nine-inch extraction shaft. The working showed that 752 cubic feet of air were discharged per minute by the fan into the extraction shaft; but of this only 325·53 cubic feet, or a little less than half the total volume extracted from the sewers, entered the sewers through the 27 soil-pipe inlets. In these ventilating soil-pipes of four-inch diameter the average velocity of the air was 226·2 feet per minute, representing an admission of 12·02 cubic feet per minute, or 5·23 cubic feet per house per minute, which is more than necessary. Therefore, the fan was utilised to ventilate a neighbouring sewer outside of the area devoted to the experiment. This reduced the volume of air extracted from the sewers and drains of the area to 142 cubic feet per minute, and of these 106·08 cubic feet were admitted through the 27 soil-pipe inlets, giving an average per house of 1·73 cubic feet per minute. This is a magnificent result, for in 24 hours the air within the house soil-pipes and drains is changed 502 times and replaced by air drawn from the outside atmosphere once in three minutes. Within the street sewers the air is changed about 309 times in the 24 hours, or once in four and a half minutes.

*The Chemical Test.*

The result thus achieved, it must be borne in mind, is absolutely independent of all climatic conditions. The wind may blow or not blow from any point of the compass, the temperature may fluctuate from the extremes of heat or cold, but still pure outer air penetrates the highest point of the soil-pipe, travels down to the lowest, then on to the sewers, bearing away all noxious effluvia and preventing any accumulation or stagnation. The sewage, if foul, is constantly swept over with fresh air; there is not time for mischief to accrue. This is confirmed by chemical analyses. Outside, but close to the area, analyses were first made of the air in the street, and it contained 3·55 parts of carbonic acid gas per 10,000 parts. In the sewer the air contained in the best samples 15·95 and in the worst 24·98 parts of carbonic acid gas per 10,000 parts of air. When, however, the nine-inch extraction shaft was applied and the system in the selected area was in working order the air in the principal street of this area was found to contain 3·18 parts of $CO_2$ per 10,000, and within the sewers the average throughout the system was 9·59 parts of $CO_2$ per 10,000 parts. On another occasion the average was only 8·08, and after that it fell to 7·04 parts of $CO_2$ per 10,000 parts. Thus there can be no doubt but that the sewer atmosphere is purified by this system of ventilation. Finally, if the air from the sewer is discharged in the street, though, of course, at as high a level as possible, it will not prove as injurious as the ordinary sewer airs, which, it has been seen, contain a much larger proportion of carbonic acid gas and whatever other impurities the excessive quantity of this gas may indicate or favour.

*The Advantages Secured.*

To fully appreciate these advantages it is necessary to bear in mind that at present in most cases the sewer airs travel up from the sewers to the houses, escape by numerous leakages, and are discharged either through grids into the streets or through various ventilating shafts, many placed against houses and near windows. Thus the current is always from the sewer to the street or the dwelling. But with mechanical power to produce a vacuum in the sewers the current is

councils, but so far as matters of public health were concerned which were most closely related to medical inspection and treatment of school children, it was the medical officers of health of the metropolitan boroughs whose coöperation was most required. No doubt it was mainly for this reason that the circulars of the Board of Education dealing with this matter made no specific reference to the problem of London, while in the Board's letter of Jan. 14th, 1911 (not yet published by the Council) special attention was drawn to the desirability of bringing the Council's school medical service into closer relation with general educational administration. A second reason put forward for placing the whole of the arrangements for medical inspection and treatment under the control of the Council's medical officer of health was that hitherto it had been the practice of the Council to provide that all work, whether administrative or professional, which was involved in the exercise of a particular profession should be placed under the direction of the professional officer concerned.

*School Medical Work closely Associated with Education.*

The subcommittee pointed out, however, that from the beginning school medical work had been closely associated with the general work of education, and proceeded to amplify this aspect of the case. The Acts under which the work was performed by the Council, as stated above, were education Acts, their objects being to secure that the children should be in a fit condition of health to profit by the education given, and also that the conditions of school environment, including such matters as sites, buildings, desks, and curriculum, should be arranged with due regard to the physical development of the children. The central administration had been entrusted, not to the department which dealt with general questions of public health (the Local Government Board), but to the department which dealt with educational administration (the Board of Education). In order to give effect to the Act of 1907 an expert medical staff had been appointed by the Board of Education to exercise general supervision over the school medical work of local authorities, and this medical staff formed part of the administrative machinery of the Board. School medical work in London had grown to its present stage in close association with the general activities of the schools and the general machinery of educational administration. The teachers played an important part in making preliminary observations on the children to be submitted to medical inspection, in giving information to school doctors and nurses, and in influencing parents to pay proper attention to the children's needs. The school medical work was also bound up very closely with the work of the local care committees which worked in conjunction with the school attendance officers, the organisers of the school meals, and others. The central care subcommittee was just as much identified with the arrangements for medical treatment as with other aspects of the physical welfare of children. From the moment when Parliament decided that inspection and treatment were to be regarded as part of the work of education, the administration of school medical work became closely linked with the general administration of education. The prominence at the moment of relief functions (provision of meals and medical treatment) tended to obscure the real nature of the organisation, but the work in all its phases was educational. School medical work was a part of this whole, and in the opinion of the subcommittee could not be removed without serious injury to the remainder.

*The Subcommittee's Conclusions.*

The subcommittee had arrived at the conclusion that the only satisfactory solution was to place the whole of the school medical work in close organic connexion with the general administration of education. The efficient carrying out of medical inspection and the arrangements for medical treatment involved a large amount of detailed work which was administrative rather than professional, such as making appointments for doctors, nurses, and children at school and at hospitals, the general organisation, the collection of charges to parents, and the filing of records. Such duties did not require expert medical knowledge, and it would be a wasteful policy to allow the time of medical men, appointed for their expert qualifications, to be occupied in superintending all the many administrative details necessary to the successful organisation of school medical work in an area as large as London. Moreover, if it were decided to detach the school medical work from the ordinary educational administration it would probably be found necessary to appoint additional organisers and assistants to carry out the medical work under the medical officer of health, leaving the present staff to carry out such duties as related to the welfare of children—the provision of meals, play centres, and after-care. Such division of work would be both unsatisfactory and uneconomical. The subcommittee therefore recommended:—

That the organisation and administration of medical inspection and treatment, including the work hitherto performed under the direction of the medical officer (education), be definitely incorporated in the Council's educational system, and placed in future under the control of the education officer, who shall be responsible to the Council, provided that the medical officer (education) shall retain his existing titles, shall have the right of access to the subcommittees of the Education Committee, and preserve his freedom and initiative as to expert advice, opinion, and investigation, and be entitled to submit reports over his own signature.

An amendment to substitute the name of the medical officer of the Council for that of the education officer led to an interesting debate, and was lost. A second amendment aimed at making the medical officer for education purposes a chief officer responsible direct to the Council. This was proposed by Mr. E. Gray, the chairman of the General Purposes Committee of the Council, "to test the feeling of the committee," and resulted in equality of voting, the chairman of the Education Committee, Mr. E. A. H. Jay, not exercising his casting vote. In the event the recommendation of the subcommittee was carried, and now awaits the confirmation of the Council.

*Progress made with Medical Inspection.*

A return presented to the committee with regard to medical inspection showed that during the week ended Feb. 4th 99 medical men had visited 145 schools and examined 11,400 children, of whom 3657 were found to require treatment for various ailments. No account was taken of defective dentition. Of the 3657 children 2293 could be provided with treatment under the Council's scheme. The work of medical inspection was shown to be somewhat in advance, as regards completeness, of the requirements of the Board of Education. To comply with those requirements 74,800 should have been examined on Feb. 4th; 78,998 had actually been examined.

*A Further Dental Treatment Experiment.*

As another step in the direction of providing dental treatment the Education Committee on Feb. 22nd decided to assist the authorities of the St. George's Dispensary, Surrey-row, Blackfriars, to resume the dental treatment service discontinued recently owing to lack of funds. Quoting the statement of the medical officer to the Board of Education that the critical time of attack on the teeth is the six-year molar period, from 6 to 8 years of age, the subcommittee which brought forward the recommendation advised that experience should be obtained at the dispensary of dealing with children of these ages as well as of other ages. In the experiments at Poplar and Deptford the age-group (8–9) was selected because children of that age were examined in the course of ordinary medical inspection. The selection of another age-period would necessitate the employment of an inspecting dentist on one half-day a week. The committee decided to set aside £400 in respect of the treatment of 1300 cases between May 1st and Dec. 31st next.

---

EDINBURGH UNIVERSITY CLUB.—The annual banquet of the Edinburgh University Club in London was held on Thursday, Feb. 23rd, at the Criterion Restaurant, Sir David Ferrier being in the chair. There were only two speeches, "The Prosperity of the Club" being proposed by the chairman, and "The Chairman" being proposed by Sir Lauder Brunton. Sir Lauder Brunton's dissertation on Sir David Ferrier's distinguished career was listened to with close attention by a numerous assemblage of guests and members of the club, for the value of his pioneer work in neurology was very clearly brought out. Sir David Ferrier, in his reply, claimed the widest recognition for the labours of Dr. Hughlings Jackson, a view which the assembled company endorsed heartily.

# Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held recently the following candidates passed in the subjects indicated:—

*Surgery.*—W. J. Gibson (Sections I. and II.), London Hospital.
*Medicine.*—M. J. A. des Ligneris (Sections I. and II.), Berne; C. B Hawthorne (Sections I. and II.), Cambridge and Birmingham; J. B. Holmes (Section I.), Manchester; J. C. Johnson (Sections I. and II.), Middlesex Hospital; and H. T. Roberts (Section II.), St. Mary's Hospital.
*Forensic Medicine.*—M. J. A. des Ligneris, Berne; D. M. Hunt, London Hospital; and H. Rowntree, Middlesex.
*Midwifery.*—H. H. Budd, St. Mary's Hospital; C. de C. W. Langdon, Manchester; J. G. Lewis, Durham; and T. T. O'Callaghan, Guy's Hospital.

The Diploma of the Society was granted to the following candidates, entitling them to practise Medicine, Surgery, and Midwifery:—W. J. Gibson, J. C. Johnson, and M. J. A. des Ligneris.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. Ludwig Jacobsohn has been granted the title of Professor. — *Budapest:* Dr. K. Pellyesniczky has been appointed to the chair of Anatomy.—*Göttingen:* Dr. Ricke has been appointed Temporary Instructor in Odontology, a private dental surgery being utilised as before.—*Greifswald:* Dr. Willy Vorkastner has been recognised as *privat-docent* of Psychiatry.—*Kiel:* Dr. A. Bauereisen has been recognised as *privat-docent* of Midwifery and Gynæcology.—*Marburg:* Dr. M. B. Schmidt of Zürich has been appointed to the chair of Pathology, and Dr. Fischer of Greifswald to the Lectureship in Dentistry.—*Naples:* Dr. Carlo Laccetti has been recognised as *privat-docent* of Surgical Diagnosis.—*Parma:* Dr. Ernesto Bertarelli has been appointed Extraordinary Professor of Hygiene.—*Sassari:* Dr. Mario Vincenzo Dettori has been recognised as *privat-docent* of Operative Medicine.—*Siena:* Dr. Arturo Guzzoni of Messina has been appointed to the chair of Clinical Midwifery.

METROPOLITAN POLICE SURGEONS' ASSOCIATION.—The annual meeting of this association, which has now reached its twenty-third year, was held at Frascati's Restaurant on Feb. 23rd. Dr. A. Dumville Roe, who has been a vice-president, was elected president for the coming year and Mr. Meredith Townsend and Dr. R. Esler vice-presidents. Dr. C. Owen Fowler and Dr. G. Nicol Henry were re-elected honorary secretaries and Dr. C. Pinel Gallie honorary treasurer, and an unanimous vote of thanks was passed thanking these gentlemen for the way in which they had fulfilled their respective arduous duties. The six vacancies on the council were filled by the election of Dr. G. A. Hamerton, Mr. P. J. Clark, Dr. G. B. Scott, Dr. Frank Shersby Smith, Mr. W. Evans, and Dr. T. Marshall. In moving the adoption of the report of the council for the past year reference was made to the loss the council had sustained owing to the retirement of Mr. W. A. Grogono, a vice-president, and Dr. J. L. Jaquet, a member of council, both having resigned through ill-health. Among other subjects which had been considered was the advisability of subsidising beds at suitable sanatoriums for the prompt treatment of early cases of tuberculous disease occurring in the police, and a deputation had represented this to the chief surgeon and the authorities at Scotland Yard. The meeting was followed by the annual dinner, which was under the chairmanship of the retiring president, Mr. Henry Bott, who was supported by Mr. C. K. Francis, one of the metropolitan police magistrates, Mr. J. Troutbeck and Mr. W. Schröder, the coroners, Major Wodehouse, C.B., of Scotland Yard, and Mr. Clinton T. Dent, the chief surgeon. After the usual loyal toasts had been honoured Mr. Francis proposed "The Metropolitan Police Surgeons' Association," and included with it that of all the members, many of whom had rendered him in his official capacity as magistrate great aid. He commented on the extraordinarily inadequate remuneration they received for their court work, which they were all so well qualified to carry out. The President-elect, Dr. Dumville Roe, in replying, laid special stress on the prosperity of the association, and paid a tribute to the great help and kind consideration that were always accorded the members by the authorities at Scotland Yard. Dr. Martindale Ward gave the toast of "The Commissioners, the Receiver, and the Chief Constables," which was replied to by Major Wodehouse and Mr. G. H. Tripp, the latter facetiously remarking that though as Receiver for the metropolitan police he was officially the enemy of divisional surgeons and might be looked upon as the skeleton of the feast, still he was at heart their friend, and he remarked how energetically the chief surgeon looked after the interests of the divisional surgeons, especially in that to them important matter, special fees. Dr. Henry proposed "The Chief Surgeon," and mentioned what a quiet revolution he had achieved, the abolition of the old station sponge which is now represented by sterilised wool, the fitting of aseptic dressing and instrument cabinets, the reduction of the number of statistical returns that were once needed and the simplification of the ones now used, all improvements effected at the expense of the last speaker, the Receiver for the metropolitan police district. Mr. Dent made a most interesting reply. Dr. Fowler expressed the satisfaction all felt at the presence of the guests, which was responded to by Mr. Troutbeck. The dinner concluded with the health of the President and Officers of the Association, to which the chairman suitably responded. Between the toasts an enjoyable concert programme was provided under the direction of Miss Edith Kirkwood, assisted by Miss Marian Jay and Mr. Stewart Gardner.

THE NEW KING'S COLLEGE HOSPITAL.—An appeal is being made by the removal committee of King's College Hospital for a further sum of £150,000 to carry on to the opening stage the work of construction of the new hospital and medical school at Denmark-hill. Sums amounting to £190,000 have been raised (exclusive of the value of the site of ten acres, amounting to £66,000, generously contributed by the Hon. W. F. D. Smith, chairman of the hospital and of the removal committee), and since the laying of the foundation-stone by King Edward building has rapidly proceeded, so that at the present time the central administration block, together with the out-patient and casualty department, bathing establishment, and the X ray and massage department above them, have been roofed in and nearly completed. It is hoped to complete wards enough to open the institution next year with 320 beds, a little more than half of the full complement of 600, and 120 more than the accommodation of the present hospital. The wards will be nine in number, on the pavilion plan, extending on rising ground to the south from the out-patient departments, administration building, and departmental buildings, which together form the frontage looking northward on Bessemer-road. The grounds extend right up to the railway cutting which divides the hospital from the beautifully wooded Ruskin Park, giving the patients all the advantages of a veritable country site in the midst of a rapidly encroaching forest of brick and mortar. The eastern block is approached from Bessemer-road by a court-yard, having on the left the casualty department with eight single-bedded, glass-walled, cross-ventilated observation wards above for the temporary isolation of suspicious out-patient cases. The entrance for in-patients is at the end of the court, and on the right is the entrance to the out-patient department, leading into a large hall capable of accommodating 500 people. This is separated by a corridor from the various consulting-rooms, so that on leaving the latter no patient will have to return to the waiting hall. In this block also is a very complete bathing establishment, with massage, X ray, and electrical departments above. The centre block is formed by the administration department, while the western wing will consist of the medical school and other departmental buildings. The ventilation and warming systems are especially worthy of notice. Apertures in the ceilings of all the rooms connect with a series of pipes on the roofs that converge to a number of large exhaust fans. Ventilators in the walls, a foot or two above the floor, are screened by the moveable radiators turning like a door on its hinges for cleansing purposes. By this means the incoming cold air will be heated by passing through the apertures in the radiators on its way. The heating will be by low-pressure steam, and the magnitude of the plant will be suggested by noting that it involves 18 miles of steam piping and seven miles of hot-water piping, while over 1000 radiators are used. There will be an ice-plant manufacturing ten tons daily. A glance at the situation of Bessemer-road, Denmark Hill, on the map of London, will indicate the large area to the poor of which this hospital will be within easy reach—Wandsworth, Balham, Brixton, Stockwell, Camberwell, Peckham, New Cross, and Deptford,

and the hope is widely felt that its out-patient department will be as far as possible consultative. A special fund is also being raised for the erection and endowment of the medical school.

THE staff of the Post-Graduate College, West London Hospital, have issued invitations for a conversazione to be held at the hospital on Wednesday, March 15th, at 8.30 P.M.

UNIVERSITY OF SHEFFIELD.—The Council at its last meeting made the following appointments:—Mr. Sinclair White, M.D., M.Ch. R.U.I., F.R.C.S. Eng., to the Professorship of Surgery in the University, in succession to Mr. R. J. Pye-Smith, resigned; Mr. George Stanfield, B.Eng. Sheffield, to the post of Demonstrator in Engineering; and Mr. Ll. Lloyd, B.Sc. Lond., to the post of Assistant Curator of the Zoological Museum.

THE EDWARD MEDAL.—At an investiture which was held by the King at St. James's Palace on Feb. 23rd His Majesty presented to Mr. E. A. Dando, M.R.C.S. Eng., L.R.C.P. Lond., the Edward Medal of the Second Class for "conspicuous gallantry on the occasion of an underground fire at the Russell Colliery, Staffs. Mr. Dando, who was summoned to the mine when the fire broke out, went down the pit and bravely assisted in the rescue work for several hours. He was at last overcome by the poisonous gases, and was brought to the surface unconscious, and did not recover from the effects of his courageous action for some time."

CENTRAL MIDWIVES BOARD.—A meeting of the Central Midwives Board was held at Caxton House, Westminster, on Feb. 23rd, Sir Francis H. Champneys being in the chair. The following letter from the Clerk of the Privy Council was received:—"26th January, 1911. To the Secretary, Central Midwives Board. Sir,—Referring to your letter of the 23rd instant, embodying certain resolutions passed at a meeting of the Central Midwives Board on the 19th instant, in regard to Clause 7 of the Midwives (No. 2) Bill, 1910, I am directed by the Lord President of the Council to state, for the information of the Board, that the proposals contained in the clause in question will not reappear in any future Bill which may be introduced on the subject, and that no deputation is therefore necessary.—I am, Sir, your obedient servant, (signed) ALMERIC FITZROY." The clause in question provides that every certified midwife shall in each year notify the Board of her address and pay a fee of 1*s.*, failing which her name shall be removed from the roll and her certificate cancelled. Mr. E. Parker Young again drew attention to Clause 11, showing that it was objectionable because it meant interference with the practice of medical men. A letter was received from the Clerk of the Council in reply to the suggestion of the Board that Section 1 (2) of the Midwives Act, 1902, should be amended by the deletion of the words "habitually and for gain," pointing out that the proposed amendment might give rise to more laxity of administration than it would prevent, as "emergency" would conceivably be more difficult to disprove than it would be to establish a practice which is habitual and for gain. A letter was received from the medical officer of health of Manchester inquiring as to the truth of a statement appearing in a report in *Nursing Notes* for January, 1911, of the Board's decision to take no action in the cases of two certified midwives against whom the local supervising authority had found *primâ facie* cases of negligence or misconduct. The Board decided to reply to both questions in the affirmative, adding that the Board acted on the finding by the local supervising authority of a *primâ facie* case which it assumes would be adequately supported by evidence capable of proof at the hearing of the case. Letters were received from the medical officer of health of Ipswich as to the Board's decision to take no further action in the case of a certified midwife against whom the local supervising authority had found a *primâ facie* case of negligence. The Board decided that the medical officer of health of Ipswich be informed that, while the Board is entirely in sympathy with any endeavour to censure or to remove from the Roll the name of a midwife who has been proved to be guilty of serious breaches of the rules, and would regret as much as the local supervising authority the failure of any such case for want of complete legal proof, the responsibility for the decision in any particular case must remain with the Board alone. The Board decided that the opinion of the Privy Council should be sought as to whether a midwife guilty of a breach of the rules when acting as a maternity nurse is amenable to the jurisdiction of the Board.

ROYAL DENTAL HOSPITAL, LEICESTER-SQUARE, LONDON, W.—The annual general meeting of the governors of this hospital will be held on March 9th, at 5.30 P.M., when Mr. E. Lloyd-Williams, vice-president, will preside.

ROYAL SOCIETY OF ARTS.—A lecture on "Plague and its Dissemination" will be given at 8 P.M. on March 8th by Mr. James Cantlie. Sir Shirley Murphy will preside.

LITERARY INTELLIGENCE.—A fifth edition of Mr. Bland-Sutton's "Tumours: Innocent and Malignant," incorporating much new matter, is announced by Messrs. Cassell and Co. for publication on March 4th.—Messrs. J. and A. Churchill have ready for publication a work entitled "The Principles of Aeroplane Construction," with calculations, formulæ, and 51 diagrams, by Rankin Kennedy, C.E., author of numerous works on engineering.

BRITISH MEDICAL BENEVOLENT FUND.—The annual general meeting of this Fund will be held on Monday, March 6th, at the rooms of the Medical Society of London, 11, Chandos-street, Cavendish-square, W., at 5 o'clock in the afternoon. Sir John Tweedy, president, will preside, and the annual report will be presented by the treasurer, Dr. Samuel West. The meeting will be later addressed by Sir Thomas Barlow, Mr. Butlin, and Professor Howard Marsh. All those interested in the Fund and Guild, ladies and gentlemen, are invited to be present. Tea will be provided before the meeting.

THE MEDICAL INSPECTION AND TREATMENT OF SCHOOL CHILDREN.—On Thursday, March 16th, at 8 P.M., in Clifford's Inn Hall, Fleet-street, a conference on these subjects has been arranged by the Fabian Education Group. Sir Victor Horsley will take the chair, and Mr. Reginald Bray, L.C.C. ("What has been done by the County Council"), Miss Margaret McMillan ("What might be done"), and Miss Marion Phillips, D.Sc., are announced to speak. Questions and debate will follow. The conference is open to all interested, who should communicate with Miss Agnes A. Crosthwaite, The Retreat, Westerham, Kent.

THE LOCAL GOVERNMENT BOARD AND THE MEDICAL TREATMENT OF OLD AGE PENSIONERS.—At a recent meeting of the Clutton (Somerset) board of guardians it was reported that the guardians had inquired of the Local Government Board whether it was the duty of the district medical officer to attend old age pensioners, and whether the guardians could legally grant medical relief for a period of three or six months to old age pensioners not otherwise paupers. The Local Government Board, in reply, stated it was the duty of the medical officer to attend old age pensioners, and that the guardians could make orders for periods of time, but it was necessary for them periodically to revise such orders.

THE ROYAL SANITARY INSTITUTE.—A meeting of this institute will be held at 90, Buckingham Palace-road, London, S.W., on March 14th, when Dr. Leonard Hill, F.R.S., will open a discussion on "Rescue Work in Mines," with a demonstration of apparatus in use. The chair will be taken at 8 P.M. by Mr. R. A. S. Redmayne, M.Sc., Chief Inspector Coal and Metalliferous Mines, Home Office.—A provincial sessional meeting will be held on March 17th in the Civil Court, Guildhall, Bristol, when a discussion will take place on Modern Methods of Purification of Public Water-supplies, to be opened by Mr. J. A. Macpherson, B.Sc., M.I.C.E. Among others the following gentlemen will take part in the discussion: Dr. D. S. Davies, medical officer of health, Bristol; Mr. Herbert Jones, medical officer of health, Herefordshire combined districts; Dr. J. M. Martin, county medical officer of health, Gloucestershire county council; Dr. W. G. Savage, county medical officer of health, Somerset county council; and Mr. J. Tubb-Thomas, county medical officer of health, Wilts county council. The chair will be taken at 10.45 A.M. by Dr. Louis C. Parkes, chairman of the council of the institute. Tickets for admission of visitors may be had on application to Mr. T. J. Moss-Flower, Carlton Chambers, Baldwin-street, Bristol, who is kindly acting as

the local honorary secretary of the meeting, and of Mr. E. White Wallis, secretary, 90, Buckingham Palace-road, London, S.W.

THE DEVON COUNTY MEMORIAL TO THE LATE KING.—The Lord Lieutenant of Devon recently appealed for the sum of £5000 to be subscribed as a county memorial to the late King. Up to the present £4595 have been received, and the remainder will doubtless shortly be raised. The money will be devoted to the provision of trained nursing for the sick poor of Devon.

DONATIONS AND BEQUESTS.—The late Mr. Joseph Shorrock, of Harewood, Disley, Cheshire, bequeathed £1000 to the National Society for the Prevention of Cruelty to Children.—The late Mr. George Newton, M.R.C.S. Eng., of Tower House, Shipley, and formerly of Dukinfield Lodge, Cheshire, has by will left among other bequests more than £36,000 to be divided between the Medical Missions Auxiliary of the Church Missionary Society and Dr. Barnardo's Homes.—The Dreadnought Seamen's Hospital has received £1000 for the endowment of a bed in memory of the late Mr. George Busk, F.R.S., past president of the Royal College of Surgeons of England, from his daughters, Miss E. Busk and Miss F. Busk.—Under the will of the late Mr. Jonathan Knowles, of Underwood Rawdon, Leeds, the Bradford Children's Hospital will receive £600 to be applied towards the permanent endowment of the "Mary Knowles" Ward.—The King of the Belgians has sent to the Liverpool School of Tropical Medicine a cheque for £500, in token of His Majesty's appreciation of the valuable work that the school is carrying on for the benefit of tropical countries.

CARNEGIE ENTOMOLOGICAL RESEARCH SCHOLARS.—With a view to furthering the work of the African Entomological Research Committee of the Colonial Office, Mr. Andrew Carnegie has placed at its disposal a sum of £1000 a year for three years to defray the cost of sending a few suitably qualified young men to the United States to study the practical applications of entomology which have received so much attention in that country. Three of these Carnegie scholars, as they are to be called, have been selected, and two of them are already at work in the United States. The fact that Dr. L. O. Howard, chief of the Bureau of Entomology at Washington, is personally interesting himself in the matter is a sufficient guarantee that all possible facilities will be given to the scholars, and it may be confidently expected that the scheme will be of great value to British administration in Africa and elsewhere by providing a body of well-trained entomologists available for employment in the services of the different colonial governments. Further particulars may be obtained from the secretary of the committee—Mr. Guy Marshall, British Museum (Natural History), South Kensington, London.

WEST SUSSEX SANITARY AUTHORITIES.—The appointment of Dr. A. G. R. Cameron, medical officer of health for the combined sanitary districts of West Sussex, as medical officer of health under the county council being considered a fitting opportunity to bring about a change in the combined districts, an important meeting of the representatives from the districts was held at Horsham on Feb. 23rd. Dr. R. D. Sweeting, an inspector of the Local Government Board, attended and gave expression to the official view on the subject. The existing combination, he said, was too unwieldy to be workable, and the Local Government Board suggested the division of the county into two parts according to its geographical suitability—the northern and southern districts with the Southdowns as the dividing line—a medical officer to be appointed to each to work in conjunction with the education authorities for school inspection, each officer to receive a minimum salary of £500 per annum. This arrangement, it was explained, could be effected with a reduction on the present expenditure. The meeting unanimously decided to adopt the suggestions of the Local Government Board as voiced by Dr. Sweeting, and the authorities concerned are to be asked to give the necessary sanction. In the course of the proceedings regret was expressed by the representatives of the combined sanitary districts upon the loss they were sustaining by the transference of Dr. Cameron to the county council; while, on the other hand, Dr. Cameron was heartily congratulated upon his success in securing the new appointment.

# Parliamentary Intelligence.

## NOTES ON CURRENT TOPICS.

*Army Hospitals.*

Mr. HALDANE, the Secretary of State for War, in his Memorandum relating to the Army Estimates for 1911-12, makes a passing reference to army hospitals. He states that the work now being done in relation to hospitals is based on a comprehensive scheme for providing large hospitals on modern lines at certain central stations, the smaller stations being provided with reception stations, and motor ambulances being used as occasion requires for the transfer of patients to the central hospitals. Under this scheme the hospitals at Arbour Hill (Dublin), Chatham, York, and Tidworth are in course of transformation into central hospitals, the expenditure at the last-named station falling on the Military Works Loan. An important new service to be commenced next year is the provision of a new central hospital for Malta, where the existing hospitals are ill-placed and out of date.

*Illegitimacy and Maternity Bill.*

A Bill has been introduced in the House of Commons by Mr. KING "to consolidate and amend the Bastardy Laws; to enable maternity orders to be made with regard to certain women and girls; to make further provision with respect to certain maternity cases dealt with under the Acts relating to the relief of the poor, and otherwise to amend the law relating to illegitimacy and for other purposes connected therewith." The Bill, which has been read a first time, is supported by Sir ROBERT PRICE, Mr. ALDEN, Mr. HENRY MCLAREN, Mr. SNOWDEN, Mr. FLETCHER, Mr. GEORGE ROBERTS, and Mr. HERBERT CRAIG.

*Nurses' Registration Bill.*

Mr. MUNRO-FERGUSON has introduced the Nurses' Registration Bill in the House of Commons. It is described as "a Bill to regulate the qualifications of trained nurses and to provide for their registration." In again bringing forward this measure the right honourable gentleman has received representative support in all quarters of the House. The Bill is "backed" by Sir JAMES GIBSON, Sir LUKE WHITE, Dr. RAINY, Dr. ADDISON, Mr. J. A. BRYCE, Viscount MORPETH, Mr. SCOTT DICKSON, Mr. REMNANT, Mr. G. YOUNGER, Mr. RAMSAY MACDONALD, and Mr. FIELD.

*Medical Graduates of the University of Wales.*

A Bill is being brought forward by Sir D. BRYNMOR JONES "to define and enlarge the rights of graduates in medicine in the University Wales."

*Rescue and Aid in Mines.*

The Departmental Committee on the organisation of rescue and aid in connexion with accidents in mines has completed a report. It will probably be published at an early date.

## HOUSE OF COMMONS.

WEDNESDAY, FEB. 22ND.

*Dresden Hygiene Exhibition.*

Mr. BYLES asked the President of the Board of Trade to state upon what grounds the promoters of the British exhibit at the forthcoming International Exhibition of Hygiene at Dresden were refused by his Department the grant which they asked for, although similar assistance had been given to the exhibition in Turin.—Mr. BUXTON replied: At the time when this country was invited to take part in the Dresden Hygiene Exhibition, the Board of Trade had already entered into engagements to organise official British sections at international exhibitions at Brussels, Buenos Aires, and Vienna in 1910, and at Rome and Turin in 1911. In these circumstances, and in view of the exacting demands made upon British manufacturers by too frequent participation in international exhibitions, the Board of Trade felt unable to undertake, or give official support to, the organisation of an exhibit of commercial products at the Dresden Exhibition of Hygiene. I have, however, expressed to the organisers of the exhibition in London the cordial interest which His Majesty's Government takes in the scientific side of this undertaking.

THURSDAY, FEB. 23RD.

*The Nutritive Value of Bread.*

Mr. GOLDMAN asked the President of the Local Government Board whether the inquiries now being made by the officers of the Board in connexion with bread included the question of the relative nutritive values of bread containing different proportions of the germ and the inner cuticle of the wheat berry, which were eliminated in the ordinary process of roller milling, and of ordinary bread containing none of these constituents.—Mr. BURNS answered: The subject referred to in the question is being considered in connexion with the inquiry into matters relating to flour and bread which is now proceeding. A preliminary report on the subject will, I hope, shortly be issued.

Mr. GOLDMAN asked the First Lord of the Admiralty whether, in view of the higher nutritive value of bread containing the germ and inner cuticle of the wheat berry over ordinary white bread, he would consider the desirability of providing that, in Admiralty contracts, no bread and flour should be supplied in which these things had been eliminated.—Mr. MCKENNA said in reply: It was the practice until recent years to supply the navy with "stone-ground" flour produced in Government mills at the victualling yards, but there was considerable prejudice amongst the men against the dark-coloured bread and puddings which this flour produced, and very little was consumed. It was consequently decided to dismantle the Government mills and to

purchase from millers the "roller-ground" flour which is used in the private trade. The bread, &c., made from this flour is very popular in the navy. Before eliciting the present opinion of the fleet on the subject it is proposed to wait until the Local Government Board experts, who are at present investigating the comparative nutritive qualities of the various descriptions of flour, have made their report.

Mr. KELLAWAY: Is the right honourable gentleman aware that, in the opinion of some of the leading millers in the country, the so-called standard bread consists of ordinary bread made with ordinary flour to which a little pig meal has been added?

Mr. MCKENNA: I was not aware of that. I can only repeat that the bluejackets who had this bread do not seem to like it.

Mr. C. DUNCAN: Before any change is made will the opinion of the men be obtained?

Mr. MCKENNA: Yes, sir. The sailors have strong opinions of their own as to whether they like food or they do not.

*Borax in the Preservation of Meat.*

Mr. HUNT asked the President of the Local Government Board whether, in view of the fact that the use of borax in the preservation of meat was a criminal offence in America and that borax was allowed to be used in specially marked boxes for exportation to this country from America, he had taken any steps to preserve the health of our people from the bad effects of American meat preserved by borax.—Mr. BURNS replied: I am advised that as far as the public health is concerned these matters are sufficiently dealt with by the regulations which have been made under the Public Health (Regulations as to Food) Act, 1907. I do not consider that further steps are at present called for.

*American Imported Meat.*

Mr. HUNT asked the President of the Local Government Board whether, in view of the fact that the American Government marked as fit and wholesome for human food the remainder of the carcasses of animals from which parts affected by tuberculosis, malignant tumours, and other diseases had been cut out, he had taken any steps to prevent such meat, either tinned, chilled, or frozen, from being sold for food in this country without due notice to purchasers as to the origin of this meat.—Mr. BURNS answered: Under the Public Health (Unsound Food) Regulations, 1908, the medical officer of health is empowered to seize any article of food landed within the district which is unsound, unwholesome, or unfit for human consumption. I do not at present think it necessary to make further provisions on the subject. I may observe that the rules laid down by the United States authorities governing the inspection of carcasses of cattle intended for export, either inter-state or foreign, are not less stringent than those observed in this country. In the case of the pig the United States standard is less stringent than that obtaining in this country, and in accordance with the provisions of the Foreign Meat Regulations, American pork, fresh chilled or frozen, is only admissible if it comes in the form of a whole carcass so as to permit of examination for disease.

Mr. HUNT: Is the right honourable gentleman aware that in this country carcasses of any animals suspected of tuberculosis or other malignant disease are altogether destroyed and under the American regulations it is not so? Is he aware that according to the American regulations the diseased parts only have to be cut off and the rest of the carcass is stamped by the American Government as sound and fit for human food?—Mr. BURNS: I have nothing to do with the American regulations, but this I do know, that there is no country in the world where the regulations as to importation of unsound, unfit, and unwholesome food are as stringently administered as in this country.

*Medical Report on Employment in Telephone Exchanges.*

Mr. WILLIAM THORNE asked the Postmaster-General whether he had now considered the report of the medical officers upon the conditions of employment in telephone exchanges, and when it was proposed to publish the same.—Mr. H. SAMUEL replied: The report has been under close consideration, and the details of its various proposals have been or are being worked out by the department. The question of publication is not yet decided.

*The Public Health Department of Egypt.*

Mr. RAMSAY MACDONALD asked the Secretary of State for Foreign Affairs whether, with reference to the resignation of Dr. E. H. Ross and Dr. H. C. Ross from the Public Health Department of Egypt, Sir Horace Pinching, the late Director-General, was consulted upon the question of what offers he made to the Drs. Ross which induced them to surrender positions in the navy in order to join the Egyptian service; whether Sir Horace Pinching had, or had not, admitted that he offered them permanent appointments in the Egyptian service; and whether the Government proposed to accept responsibility for the actions of its responsible officers and accredited agents in Egypt.—Sir EDWARD GREY replied: Dr. E. H. Ross held an appointment on the permanent staff of the Egyptian Public Health Department until his resignation, which, it is understood, took effect from the beginning of this month. From a letter addressed by Sir Horace Pinching to Dr. H. C. Ross (dated May 25th, 1906), a copy of which has been communicated to me, it is evident that this gentleman's appointment was temporary. I would refer the honourable Member to the reply I returned to his question of May 25th, 1909. The reply to the last part of this question is in the affirmative, but I must point out that officials of the Egyptian Health Department are in the service of the Egyptian and not of His Majesty's Government.

*The Water-supply of Cairo.*

Mr. RAMSAY MACDONALD asked the Secretary of State for Foreign Affairs whether his attention had been drawn to the proposal of Dr. Graham, the Director-General of the Public Health Department, Cairo, to take the water-supply for the town from a point in the Nile below the town; whether the Foreign Office had any power to prevent the carrying out of this scheme; and whether it was possible for the Foreign Office to consult the previous directors of the Public Health Department, like Sir Horace Pinching, on Dr. Graham's proposal.—Sir EDWARD GREY answered: I would refer the honourable Member to pages 34 and 35 of the report from His Majesty's Agent and Consul-General at Cairo for the year 1909, where the subject is fully dealt with. His Majesty's Government do not propose to address the Egyptian Government with regard to this question, which, as the honourable Member will see, has been so thoroughly investigated by the most competent experts in Egypt.

MONDAY, FEB. 27TH.

*Vaccination of Children.*

Mr. CRAWSHAY-WILLIAMS asked the President of the Local Government Board whether any cases of small-pox had occurred in England amongst children since the passing of the Vaccination Act, 1907, and, if so, whether any of those patients had been exempted from vaccination under the conscience clause of that Act.—Mr. BURNS replied: Cases of small-pox have occurred amongst children since the passing of the Vaccination Act. Their number cannot be given, but in the two years 1908 and 1909 the number of deaths from small-pox of children under 15 recorded by the Registrar-General was six. Four of these cases are stated to have been unvaccinated; in the other two cases it is doubtful whether they had been vaccinated or not. I have no information as regards these six deaths whether certificates of exemption from vaccination had been obtained.

*Arm-to-Arm Vaccination in Scotland.*

Mr. WEIR asked the Lord Advocate whether, in view of the fact that arm-to-arm vaccination had long since been abolished in England with satisfactory results, the Secretary for Scotland would take such steps as might be necessary to secure its abolition in Scotland.—Mr. URE replied: The practice of arm-to-arm vaccination is almost, if not quite, obsolete in Scotland, but it could not be directly abolished without further legislation. The Local Government Board invariably recommends the use of glycerinated calf lymph and supplies it free of charge to parish vaccinators. I may add that during the last two years no applications for humanised lymph were received by the department.

*The Anti-Malaria Campaign at Cairo.*

Mr. RAMSAY MACDONALD asked the Under-Secretary of State for Foreign Affairs whether an anti-malaria campaign, carried on in Cairo in 1907, had been interrupted by a disagreement between the medical and administrative authorities, with the result that mosquito destruction had been stopped and that malaria had reappeared in districts where the 1907 campaign had almost stamped it out; whether he had any knowledge that recently repeated requests had been made by the inhabitants of Cairo to the sanitary department to re-initiate the mosquito campaign; and whether the Foreign Office proposes to bring more pressure to bear upon those responsible for the public health of Cairo, so that obvious precautions might be taken against malaria.—Mr. MCKINNON WOOD answered: I have no more recent information on this subject than that given in the 1909 report from H.M.'s Agent and Consul-General at Cairo, but I will ask for a report on the points raised in this question.

*The Weir Hospital Charity.*

Mr. PIKE PEASE (on behalf of Sir HENRY KIMBER) asked the honourable Member for the Stroud Division, as representing the Charity Commissioners, whether, in view of the fact that the order of the Charity Commissioners establishing a scheme for the administration of the Weir Hospital Charity was discharged by the order of the Court of Appeal so long ago as June 7th, 1910, and the matter was remitted to the Commissioners to administer the charity in accordance with the directions of the testator, there was any reason why a scheme for the proper administration of the charity had not yet been published; and what steps had been, or were likely in the near future to be, taken by the Commissioners to give the parish of Streatham the benefits of the charity bequeathed to them.—Mr. C. P. ALLEN replied: The Charity Commissioners have been, and are still, in communication with the trustees of Mr. Weir's will as to the provisions of a new scheme. The honourable Member may be assured that the new scheme will be framed in accordance with the views expressed by the Court of Appeal for the establishment and maintenance at the testator's residence of a cottage hospital which will be, as directed by him, for the benefit of the inhabitants of Streatham and the neighbourhood.

TUESDAY, FEB. 28TH.

*Small-pox in London.*

Mr. COOPER asked the President of the Local Government Board how many cases of small-pox had been reported in the County of London since Jan. 1st, 1911, and how many of these cases had been vaccinated.—Mr. BURNS replied: From Jan. 1st to the evening of yesterday 41 cases were notified and removed to the Metropolitan Asylums Board's Hospitals. Of the 36 cases in the hospitals of the Asylums Board on Sunday evening last 29 were vaccinated and 7 were unvaccinated. In 24 of the cases vaccination was performed more than 15 years ago and in two others at least 10 years ago. The three other vaccinated cases were those of children, and the attack is said to be mild.

Mr. HARRY LAWSON asked whether the attention of the right honourable gentleman had been called to the outbreak of small-pox in the East-End of London; and whether he was satisfied that all proper steps were being taken to deal with it by the Metropolitan Asylums Board and the other local authorities.—Mr. BURNS answered: My attention has, of course, been drawn to this outbreak, and my officers have been inquiring into it. The reports I have received show that all the authorities concerned are, through their officers, taking active measures to deal with the outbreak. Should the disease assume wider dimensions, no doubt these measures may require to be supplemented.

*Small-pox Hospitals in Scotland.*

Mr. MUNRO-FERGUSON asked the Lord Advocate whether it was the view of his Department that vaccination no longer deserved encouragement and that the best precaution against small-pox was an ample provision by local authorities of small-pox hospitals; and whether the Government intended to make any contribution towards the cost of providing small-pox hospitals.—Mr. URE answered: The view suggested by my right honourable friend is not that of the Government, nor is there, so far as I am aware, any fund out of which the suggested contribution could be made.

*Precautions against Plague.*

Earl WINTERTON asked the President of the Local Government Board what steps had been taken at the Channel ports medically to examine persons arriving from districts in Eastern Europe where plague existed.—Mr. BURNS wrote in reply: The Local Government Board's Order of 1909 requires the Customs' officer on the arrival of a ship from a foreign port to ascertain whether the ship is an infected ship or has come from an infected port and to question the captain. At the present time the only district in Eastern Europe known to be affected with plague is in the government of Astrakhan on the Asiatic borders,

an area inhabited by nomadic tribes who are unlikely to travel to these islands by train and the Channel passage.

*Public Slaughter-houses in Scotland.*

Mr. WATT asked the Lord Advocate to state the number of burghal local authorities in Scotland who have public slaughter-houses, and the number of such local authorities who had appointed or employed veterinary surgeons under the Public Health (Scotland) Act, 1897, and the Dairies, Cowsheds, and Milkshops Orders; and would he say how many burghal local authorities had not adopted any of these courses.—Mr. URE said in reply: The most recent returns for the year 1909 show that in that year there were 123 burghs in Scotland which had public slaughter-houses and 82 which had not. Every burghal local authority in Scotland has approved one or more veterinary surgeons for the purposes of the Public Health (Scotland) Act, 1897, and of the Order referred to by my honourable friend.

*Bakehouses and Public Health.*

In reply to Mr. WILKIE, Mr. CHURCHILL said: The whole question of conditions of work in bakehouses, in regard to the effect both on the health of the workers and on the public health, is being made the subject of investigation by my department in conjunction with the Board of Trade and the Local Government Board, and until the inquiries are completed I am afraid I can make no statement on the question of legislation.

*Hospital Accommodation at Rosyth.*

Major ANSTRUTHER GRAY asked the First Lord of the Admiralty whether, in view of the number of men employed at Rosyth, he would use his influence and secure them improved hospital accommodation which was reported to be inadequate.—Mr. MCKENNA replied: The care of the men employed on the dockyard works at Rosyth is entirely in the hands of the contractors, and I am not aware that the contractors' arrangements are inadequate.

# Births, Marriages, and Deaths.

## BIRTHS.

FAIRLIE CLARKE.—On Feb. 24th, at Horsham, Surrey, the wife of A. J. Fairlie Clarke, M.C., F.R.C.S., prematurely, of twin sons (one stillborn).

HENDERSON.—On Feb. 24th, at Rodney-street, Liverpool, the wife of Dr. W. Savile Henderson, of a son.

HOLLAND.—On Feb. 23rd, in Edinburgh, the wife of H. Tristram Holland, F.R.C.S.E., C.M.S. Hospital, Quetta, of a son.

STREET.—On Feb. 21st, at Cranfield, Woburn Sands, the wife of Albert Ernest Street, M.R.C.S., L.R.C.P., of a daughter.

## DEATHS.

MACPHERSON.—On Feb. 22nd, at Whitehall Park, Highgate, N., Peter Macpherson, M.D., in his 75th year.

*N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

# Notes, Short Comments, and Answers to Correspondents.

## THE VARYING CAPACITY OF TEASPOONS.

ATTENTION has again been called to the possible variations in the capacity of teaspoons by a pharmacist who took the trouble to collect a number of teaspoons from different customers. He found them to vary in capacity from 90 to 120 minims. The attention of the pharmacist was drawn to the matter by the complaint of a customer for whom he had dispensed a mixture containing 2 grains of morphine sulphate in an ounce mixture the dose of which was 1 drachm every hour until relieved. After the third dose had been taken the customer complained of distressing effects, and upon investigation it was found that he was using a teaspoon which held 110 minims, and was therefore taking much more than the dose prescribed. In the days of the old-fashioned silver teaspoons the variation in capacity was almost negligible, but since the introduction of electroplate makers seem to vie with each other in increasing the size of spoons. Dessertspoons and tablespoons also vary considerably in measurement, and prescribers would be well advised to insist upon their patients using graduated measures. In these days of standardised galenical preparations and scientific prescribing the teaspoon a a measure is obviously out of place.

## ENCEINTE.

*To the Editor of* THE LANCET.

SIR,—I should also like to call attention to the Second Book of Kings, chapter iv., verses 16 and 17, where Elisha addresses the Shunammite. They are as follows: "And he said, About this season, according to the time of life, thou shalt embrace a son. And she said, Nay, my lord, thou man of God, do not lie unto thine handmaid. And the woman conceived, and bare a son at that season that Elisha had said unto her, according to the time of life." The word "embrace" is the word to which I wish to draw attention. The French Bible says "tu embrasseras un fils" and the Spanish Bible reads "Abrazarás un hijo." It seems to me that in this expression the word "embrace" means to "embrace in the womb," and if it does mean so it would show that the idea of encompassing by the womb is very old, and that therefore "enceindre" may well mean encompass in like manner.

For those who prefer to accept the etymology *incincta* in the sense of *non cincta*, it must not be forgotten that even Landais himself, who made a special feature of etymology in his dictionary, admits "that the Spanairds, by a kind of antiphrasis, say of a femme grosse, that she is *en cinta*, in girdle." Even old Spanish dictionaries state that "estar la muger en cinta" means to be with child. The haughty Spaniards seem to have defied the etymology of their learned Bishop, Isidore of Seville, but the French treat him with more respect.

I am, Sir, yours faithfully,

Feb. 25th, 1911. BLANCUS.

## AN INCOMPATIBLE MIXTURE, CHLORAL AND MAGNESIA.

AT a recent meeting of the Pharmaceutical Society in Edinburgh Mr. Donald McEwan called attention to an incompatible mixture of a somewhat unusual character. A prescription, of which the ingredients were syrup of chloral, heavy magnesia, ipecacuanha wine, tincture of belladonna, and water, was duly dispensed, and on the following day the prescriber brought the bottle to the pharmacist, saying that he meant to give his patient syrup of chloral, but was afraid the dispenser must have dispensed spirit of chloroform instead. Notwithstanding that the prescription had been accurately dispensed it was evident from the smell that chloroform was present. Subsequent experiments demonstrated that the chloroform resulted from reaction between the chloral hydrate and the magnesia. In this mixture the sedative action of the chloral, which was the aim of the prescriber, is lost, and instead each dose contains about 3 minims of chloroform and 2½ grains of magnesium formate. Another important point is that the alkaloids of the belladonna and ipecacuanha are liberated by the magnesia, and completely separated and carried down by the globules of chloroform. The prescriber solved the difficulty by omitting the magnesia.

## HEALTH MATTERS IN BRITISH GUIANA.

A REPORT on the Blue-Book of British Guiana for 1909–10, prepared by Mr. J. Hampden King, Assistant Government Secretary, has been received at the Colonial Office and presented to both Houses of Parliament. The section devoted to vital statistics and public health gives the present estimated population of the Colony as 305,097—158,435 males and 146,662 females. The birth-rate for 1909 was 29·3 per 1000 of the population, the mean rate for the previous five years having been 30·4. Of the births registered 3577, or 40 per cent., were legitimate, and 5370, or 60 per cent., were illegitimate. The birth-rate per 1000 of the estimated population of each of the different races represented in the community was as follows:—Europeans (other than Portuguese), 11·1; Portuguese, 23·8; East Indians, 27·6; Chinese, 32·2; Aborigines, 61·3; blacks, 30·9; and mixed races, 27·5. The death-rate was 30·0 per 1000, as compared with a mean rate for the previous five years of 30·5. The mortality amongst children under one year continues to be high, and the mean rate for the past five years has been 210 per 1000. The health of the colony showed no marked improvement over the previous year. There was no epidemic of any dangerous, infectious, or contagious disease, though the existence of yellow fever and plague in neighbouring places gave rise to considerable anxiety. Malarial fever continues to claim a large number of victims, and efforts are being made by legislative and other action to control the mosquito pest. Quinine is now sold at the district post-offices all over the colony at cost price, and its use is steadily increasing. In 1909–10 some 2076 ounces were thus sold. Steps were taken to procure this drug put up in chocolate with a view of increasing its consumption among the children, but this method has proved too expensive. The Medical Department continues to give attention to the question of ankylostomiasis, and the interest that has been aroused in this connexion among the employers of labour on the sugar estates and among the labourers themselves is bearing fruit.

There were a few sporadic cases of enteric and blackwater fevers, but, as usual, the principal causes of death were malarial fevers, diarrhœal diseases, and phthisis and other forms of tuberculosis. Professor Deycke's system of treatment of leprosy by "nastin" is being steadily followed at the leper asylums on the lines laid down by him. Several cases have so much improved that it is hoped they may shortly be discharged. There are five public hospitals in the principal centres of population, and the outlying districts are served by dispensary hospitals and dispensaries. The immigration law also requires the maintenance of hospitals on every plantation on which there are indentured East Indian labourers, and these institutions are available for the treatment of emergency and pauper cases from the general community. The daily average number of in-patients was 705. There were 18·90 deaths. Outdoor treatment was given to 74,646 persons.

An Ordinance has been passed which gives power to take special measures of precaution in case the colony is threatened with an invasion of a dangerous epidemic disease which the ordinary law is inadequate to deal with. The idea is to have the means of at once dealing with any dangerous disease which makes its appearance, instead of having to wait till the legislature can give the necessary special powers, and to avoid a delay during which the disease might make serious headway. It may be of interest to mention that an Ordinance has also been passed withdrawing all protection from carrion crows and permitting them to be killed like vermin in any part of the colony. Until lately they were thought to be useful as scavengers and were protected from destruction, it being an offence to kill them; but it is now agreed that they are dangerous as disseminators of disease by fouling water, and that any usefulness they possess is more than counterbalanced by the risk of spreading infection.

**COMMUNICATIONS not noticed in our present issue will receive attention in our next.**

## A DIARY OF CONGRESSES.

WE shall publish this diary from time to time that our readers may have under their hands the dates of the approaching scientific Congresses. It is unnecessary to issue the lists of all these functions week by week, and we propose to make only such gatherings as will occur in the immediate future the subject of regular announcement. The following Congresses, Conferences, and Exhibitions are announced for March, and April, 1911:—

March 2nd–6th (Berlin).—Thirty-second Balneological Congress.
,, 23rd (Paris).—First Congress of French Medical Journalists.
,, 28th–April 25th (Tunis).—Exhibition of Hygiene.
April 4th–7th (London).—Fourth Annual Nursing and Midwifery Conference and Exhibition.
,, 18th–20th (Paris).—Third Congress of Physiotherapy of French-speaking Physicians.
,, 18th (Berlin).—Tenth Congress of the German Orthopædic Surgery Society.
,, 19th–22nd (Berlin).—German Surgical Congress. (Fortieth Annual Meeting.)
,, 19th–22nd (Wiesbaden).—Twenty-eighth German Congress of Internal Medicine.
,, 20th–22nd (Groningen).—Thirteenth Nature and Medical Congress.

# Medical Diary for the ensuing Week.

## SOCIETIES.

**ROYAL SOCIETY OF MEDICINE, 15, Cavendish-square, W. (temporary address during building of new house).**

FRIDAY.

GENERAL MEETING OF FELLOWS at 4.45 P.M.
Election of Candidates for Fellowship.

CLINICAL SECTION (Hon. Secretaries: A. Carless, J. Galloway): at 8 P.M.
Dr. Lediard (Carlisle); Benign (Bone) Cyst of Tibia.
Dr. James Collier and Mr. P. Lockhart Mummery: Tabes Dorsalis, with Very Early Rectal Crises.
Mr. R. J. Godlee: Two Unusual Cases of Disease of the Thyroid Gland.
Mr. Arthur Evans and Dr. C. H. Pring: Partial Removal of the Thyroid Gland in Graves's Disease.
Dr. Leonard Guthrie: Congenital, Hereditary, Familial Pes Cavus. And other Cases.
Mr. Arthur Evans: Report on the Subsequent History and Present Condition of a Case of Excision of the Larynx (shown Nov. 12th, 1909).

**MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.**

MONDAY.—9 P.M., Lettsomian Lecture:—Mr. W. F. Haslam: A Review of the Operations for Stone in the Male Bladder. (Lecture III.)

**HUNTERIAN SOCIETY, London Institution, Finsbury-circus, E.C.**

WEDNESDAY.—8.30 P.M., Mr. J. Sherren: The Diagnosis of Gall Stones.—Dr. H. L. Tidy: Arsenic Poisoning.

**OPHTHALMOLOGICAL SOCIETY, 11, Chandos-street, Cavendish-square, W.**

THURSDAY.—8 P.M., Card Specimens by Mr. Grimsdale, Mr. W. H. Brailey, and Mr. F. A. Juler. 8.30 P.M., Papers:—Dr. H. Griffith: Three Cases of Optic Nerve Tumour.—Mr. J. Taylor: A Morgagnian Cataract Operation; Remarks.—Mr. F. Thomas and Mr. G. Coats: A Peculiar Granuloma of the Retina.

**CHILD STUDY SOCIETY, LONDON, 90, Buckingham-Palace-road, S.W.**

THURSDAY.—7.30 P.M., Mr. S. Macpherson: Appreciative Music Study, its Application in the Training of the Child.

**HARVEIAN SOCIETY OF LONDON, Stafford Rooms, Titchborne-street, Edgware-road, W.**

THURSDAY.—8.30 P.M., Discussion on Colitis (opened by Dr. S. Phillips and Mr. D'Arcy Power).

## LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.**

**At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic (2 P.M.) Hospitals operations are performed daily.**

## EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.*

*Lectures, original articles, and reports should be written on one side of the paper only,* AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

*Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.*

*We cannot prescribe or recommend practitioners.*

*Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."*

*Letters relating to the publication, sale and advertising departments of* THE LANCET *should be addressed "To the Manager."*

*We cannot undertake to return MSS. not used.*

## MANAGER'S NOTICES.

### THE INDEX TO THE LANCET.

The Index and Title-page to Vol. II. of 1910 were given in THE LANCET of Dec. 31st, 1910.

### VOLUMES AND CASES.

VOLUMES for the second half of the year 1910 are now ready. Bound in cloth, gilt lettered, price 16*s.*, carriage extra.

Cases for binding the half-year's numbers are now ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

### TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

| FOR THE UNITED KINGDOM. | | TO THE COLONIES AND ABROAD. | |
|---|---|---|---|
| One Year ... ... ... | £1 1 0 | One Year ... ... ... | £1 6 0 |
| Six Months ... ... ... | 0 12 6 | Six Months ... ... ... | 0 14 0 |
| Three Months ... ... | 0 6 6 | Three Months ... ... | 0 7 0 |

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rate of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

### TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at these rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND Co., 51, Fifth Avenue, New York, U.S.A.

## METEOROLOGICAL READINGS.
